

Indicateurs de qualité en oncologie : cancer du testicule

KCE reports 149B

Le Centre fédéral d'expertise des soins de santé

Présentation : Le Centre fédéral d'expertise des soins de santé est un parastatal, créé le 24 décembre 2002 par la loi-programme (articles 262 à 266), sous tutelle du Ministre de la Santé publique et des Affaires sociales, qui est chargé de réaliser des études éclairant la décision politique dans le domaine des soins de santé et de l'assurance maladie.

Conseil d'administration

Membres effectifs : Pierre Gillet (Président), Dirk Cuypers (Vice président), Jo De Cock (Vice président), Frank Van Massenhove (Vice président), Yolande Avondtrootd, Jean-Pierre Baeyens, Ri de Ridder, Olivier De Stexhe, Johan Pauwels, Daniel Devos, Jean-Noël Godin, Floris Goyens, Jef Maes, Pascal Mertens, Marc Moens, Marco Schetgen, Patrick Verertbruggen, Michel Foulon, Myriam Hubinon, Michael Callens, Bernard Lange, Jean-Claude Praet.

Membres suppléants : Rita Cuypers, Christiaan De Coster, Benoît Collin, Lambert Stamatakis, Karel Vermeyen, Katrien Kesteloot, Bart Ooghe, Frederic Lernoux, Anne Vanderstappen, Paul Palsterman, Geert Messiaen, Anne Remacle, Roland Lemeye, Annick Poncé, Pierre Smiets, Jan Bertels, Catherine Lucet, Ludo Meyers, Olivier Thonon, François Perl.

Commissaire du gouvernement : Yves Roger

Direction

Directeur général Raf Mertens

Directeur général adjoint: Jean-Pierre Closon

PREFACE

Lorsqu'un patient doit faire face à un cancer, il est en droit d'attendre les meilleurs soins possibles, en vue d'augmenter ses chances de survie. La responsabilité des soins de qualité relève en première instance des praticiens de santé qui d'une manière ou d'une autre sont impliqués dans le processus diagnostique et thérapeutique. L'oncologue, le chirurgien, le médecin généraliste, le radiothérapeute et bien d'autres encore, peuvent faire la différence tant au niveau de la survie que de la qualité de vie. Les autorités et le système de santé au sens large doivent ici aussi prendre leurs responsabilités, et ce dans plusieurs domaines

L'instauration d'un programme de soins personnalisés pour tous les nouveaux patients cancéreux est l'une des initiatives du Plan National de lutte contre le Cancer 2008-2010. Dans ce cadre, le développement d'un système de qualité en oncologie a toute sa place en Belgique.

En guise de préparation à la mise sur pied d'un tel système, la Ministre a demandé au KCE d'évaluer la faisabilité et la pertinence d'un système d'indicateurs de qualité pour un cancer fréquent, à savoir le cancer du sein, et pour un cancer rare, le cancer du testicule, comme il l'avait déjà fait pour le cancer du rectum dans le cadre du projet PROCARE.

Ce rapport s'appuie sur les recommandations nationales de bonne pratique clinique, publiées récemment pour les deux types de cancer (Rapports KCE I42 et I43). La pièce finale, consistant à mettre au point un système opérationnel permettant de suivre la qualité des soins en oncologie, fera l'objet d'un prochain rapport.

Dans ce rapport, nous discutons du développement d'un ensemble d'indicateurs de qualité pour le cancer du testicule. Le rapport relatif au cancer du sein est publié en parallèle. Nous espérons qu'ensemble, ils contribueront à l'amélioration de la qualité des soins délivrés aux patients.

Jean Pierre CLOSON
Directeur général adjoint

Raf MERTENS
Directeur général

Résumé

INTRODUCTION

En 2004, le projet PROCARE (PROject on CANcer of the REctum) a été initié en qualité de projet multidisciplinaire piloté par la profession. Son objectif premier était de réduire la variabilité diagnostique et thérapeutique et d'améliorer les résultats chez les patients souffrant de cancer rectal. Cet objectif a été poursuivi grâce à la standardisation des pratiques préconisée par les recommandations de bonne pratique, à la mise en œuvre desdites recommandations et à l'assurance de qualité via un enregistrement et une communication des résultats obtenus. En 2005, un registre de données cliniques spécifiques au cancer du rectum a été mis sur pied au Registre Belge du Cancer (RBC). Dans le but de permettre un feedback individuel de même qu'une comparaison nationale/internationale, un système d'indicateurs de qualité a été mis en place en 2008. Jusqu'à présent, deux rapports d'analyse des données ont déjà été communiqués aux centres participants.

En guise de préparation à la mise sur pied d'un système de qualité pour l'oncologie en Belgique, la Ministre a demandé au KCE d'appliquer les leçons tirées du projet PROCARE pour un cancer fréquent, à savoir le cancer du sein, et un cancer rare, le cancer du testicule.

Les principales questions de recherche sont :

1. La création d'un ensemble d'indicateurs de qualité pour le cancer du sein et le cancer du testicule est-elle faisable en utilisant les bases de données administratives existantes ? Plus précisément, quelle serait la valeur ajoutée du Résumé Clinique Minimum (RCM) et du Résumé Financier Minimum (RFM) ?
2. Quels systèmes/méthodes/structures sont décrits dans la littérature pour assurer le suivi de la qualité des soins en oncologie ? Cette question de recherche sera abordée dans un rapport ultérieur.

Dans un premier temps, les recommandations nationales ont été actualisées et publiées pour les deux types de cancer (Rapports KCE 142 et 143). Dans un second temps, un ensemble d'indicateurs de qualité a été développé. Le présent rapport fait état de l'élaboration de l'ensemble d'indicateurs de qualité pour le cancer du testicule. Le rapport sur le cancer du sein sera publié en parallèle.

INDICATEURS DE QUALITÉ: PROCESSUS DE SÉLECTION ET D'ÉLABORATION

METHODES

Des recherches de littérature ont été conduites aussi bien dans la base de données Medline (OVID) que dans la littérature grise, afin d'identifier les indicateurs de qualité publiés et validés pour le cancer du testicule. Les sites internet suivants ont aussi été consultés : National Quality Measures Clearinghouse, Agency for Healthcare Research and Quality, Joint Commission (USA), Clinical Indicators Support Team (UK) et sur le site du National Health Service (UK). Les indicateurs de qualité inclus dans les recommandations de bonne pratique clinique (RBP) et identifiés lors de la mise à jour des recommandations belges ont également été évalués. Les recherches de littérature ont été menées en décembre 2009. Les indicateurs de qualité dérivés des recommandations belges ont été ajoutés à la liste des indicateurs de qualité provenant de la recherche de littérature.

La procédure de sélection a été assurée de manière indépendante par 6 experts. Les critères de sélection étaient, respectivement, la fiabilité, la pertinence, l'interprétabilité et le potentiel d'action.

RESULTATS

Au total, un indicateur a été trouvé dans la littérature et 31 indicateurs de qualité ont été formulés sur la base des RBP belges. De la liste finale de 32 indicateurs de qualité, 12 ont été retenus (Tableau 1).

Tableau 1. Sélection finale des indicateurs de qualité pour le cancer du testicule

Indicateur	Type d'indicateur
Diagnostic et stadification	
Part des patients atteints d'un cancer du testicule chez qui une évaluation des marqueurs tumoraux est réalisée avant tout traitement	Processus
Part des patients atteints d'un cancer du testicule chez qui une tomographie assistée par ordinateur avec agent de contraste (CE-CT) ou une imagerie par résonance magnétique (IRM) est réalisée aux fins de la stadification primaire	Processus
Part des patients atteints d'un cancer du testicule ayant été débattus lors de la Concertation Oncologique Multidisciplinaire (COM)	Processus
Traitement	
Nombre de patients atteints d'un cancer du testicule qui sont traités chirurgicalement par centre chaque année	Processus
Dose et champ d'irradiation chez les patients atteints de cancer du testicule qui sont traités par radiothérapie, par stade	Processus
Part des patients atteints d'un non-séminome au stade I sous surveillance active	Processus
Part des patients bénéficiant d'une tomographie assistée par ordinateur avec agent de contraste (CE-CT) ou d'une IRM pour l'évaluation des masses résiduelles au terme d'un traitement systémique	Processus
Degré et durée de la surveillance active chez les patients souffrant d'un non-séminome ou d'un séminome au stade I	Processus
Part des patients souffrant d'une récurrence d'un cancer du testicule après un traitement curatif qui sont enrôlés dans un essai clinique	Processus
Indicateurs génériques	
Survie globale à 5 ans par stade	Résultat
Survie à 5 ans spécifique à la maladie par stade	Résultat
Survie à 5 ans indemne de la maladie par stade	Résultat

INDICATEURS DE QUALITÉ : MESURABILITÉ

MÉTHODES

Afin d'analyser la mesurabilité de ces indicateurs, trois bases de données différentes ont été combinées. La sélection primaire a porté sur tous les patients ayant un cancer du testicule (selon la Classification Internationale des Maladies version 10, code C62 : néoplasme malin du testicule), enregistrés dans la base de données du Registre Belge du Cancer (RBC), et ayant une date d'incidence comprise entre le 01/01/2001 et le 31/12/2006. Pour ces patients, les données du RBC ont été liées à celles de l'AIM (2001-2006) et du RCM-RFM (2002-2006). Une sélection supplémentaire a été réalisée utilisant les codes ICD-9-CM dans la base de données RCM-RFM en vue d'évaluer l'exhaustivité de la sélection primaire.

Pour chaque indicateur de qualité sélectionné, le numérateur et le dénominateur (ainsi que leurs critères d'inclusion et d'exclusion respectifs) ont été définis et la mesurabilité des critères a été évaluée.

Pour chaque indicateur de qualité mesurable, les résultats ont également été traités par centre, ce dernier restant anonyme. La variabilité entre les centres est présentée graphiquement au moyen de 'funnel plots'.

RÉSULTATS

Mesurabilité des indicateurs de qualité

Des 12 indicateurs sélectionnés, 5 ont été retenus comme étant mesurables, l'un était partiellement mesurable et deux indicateurs l'étaient en utilisant un indicateur approché (proxy) ou des informations approchées. Les 4 indicateurs restants n'ont pu être mesurés. La principale raison de l'impossibilité de mesure était l'absence de codes administratifs (n=2) ou le manque de spécificité des codes administratifs existants (n=3). Tant que des données nationales suffisamment récentes sur les causes de décès ne sont pas disponibles, la survie spécifique à la maladie n'est pas mesurable en tant que telle. La survie relative (survie observée/survie attendue) a été utilisée comme indicateur approché de la survie spécifique à la maladie.

L'un des objectifs du présent rapport consistait en l'évaluation de la valeur ajoutée des données RCM pour accroître la mesurabilité des indicateurs étudiés. Cependant, de nombreux problèmes techniques ont abouti à une corrélation incomplète entre les données RCM et les données couplées RBC-AIM. Finalement, les données couplées RBC-AIM-RCM n'étaient disponibles que pour les années 2002-2004 et pour un nombre limité de cas (environ 70%). Les données RCM ont contribué à améliorer la mesurabilité des indicateurs impliquant le traitement chirurgical (volume chirurgical, part de patients au stade I traités par surveillance active). S'il devait y avoir un code de nomenclature plus spécifique pour l'orchidectomie, l'information complémentaire apportée par les données RCM deviendrait redondante. La valeur ajoutée des données RCM pour les autres indicateurs n'a pas été établie. Par ailleurs, en raison des problèmes techniques précités, les données RCM n'ont pas pu contribuer à évaluer l'exhaustivité des données RBC.

Résultats au niveau national

Le Tableau 2 montre l'évolution entre 2001 (N patients = 209) et 2006 (N patients = 248) pour la plupart des indicateurs mesurables. Les résultats suivants sont analysés plus en détail dans le rapport scientifique :

- Le taux de survie à 5 ans est élevé et reste en légère augmentation. Ce résultat suit la même tendance que celle observée dans d'autres pays. Contrairement aux autres pays, aucune différence n'a été observée entre les séminomes et les non-séminomes pour ce qui concerne la survie relative à 5 ans.
- Le recours aux marqueurs tumoraux dans la mise au point diagnostique est modéré à bon.

- La concertation oncologique multidisciplinaire (COM) gagne en intérêt mais, en comparaison avec d'autres types de tumeur, la proportion est assez faible.
- Le taux d'orchidectomie paraît faible. Des explications possibles avancées par les experts sont le recours à un code de nomenclature erroné, voire l'absence de recours à un code (en l'absence de code spécifique dans la nomenclature pour l'orchidectomie radicale 'simple').
- Le taux de surveillance active chez les patients au stade I est faible.
- Aucune information n'est disponible en ce qui concerne le nombre de patients enrôlés dans des essais cliniques.

Tableau 2. Evolution des indicateurs de qualité mesurables entre 2001 et 2006.

Indicateur	Résultats 2001	Résultats 2006
Survie observée à 5 ans	91%	94% (résultats 2004)
Survie relative à 5 ans	92%	95% (résultats 2003)
Part des patients atteints d'un cancer du testicule chez qui une évaluation des marqueurs tumoraux est réalisée avant tout traitement	72.3%	80.6%
Part des patients atteints d'un cancer du testicule ayant été débattus lors de la Concertation Oncologique Multidisciplinaire (COM)	53.1% (résultats 2004)	67.3%
Nombre de patients atteints d'un cancer du testicule qui sont traités chirurgicalement	81.3%	81.0%
Part des patients atteints d'un non-séminome au stade I qui sont traités par surveillance active	28.0%	20.0%
Nombre moyen d'évaluations des marqueurs tumoraux au cours de la surveillance active durant la première année suivant la chirurgie chez les patients atteints :		(résultats 2005)
• D'un séminome	5.5	6.5
• D'un non-séminome	10.5	8.9

Comparaison entre les centres

Les résultats provenant des statistiques descriptives ainsi que des indicateurs de qualité mesurables montrent une variabilité considérable entre les différents centres. Cette variabilité est plus marquée dans le cas des indicateurs de processus, même si une certaine variation est également présente en termes de survie.

Il est frappant de constater la fragmentation des soins pour les patients atteints d'un cancer du testicule. De toutes les orchidectomies pratiquées pour cause de cancer du testicule entre 2004 et 2006, 40% ont été réalisées dans 14 centres, les 60% résiduels ayant été effectuées dans 83 centres. Plus d'un tiers des centres traitant les patients atteints de cancer du testicule ont pratiqué en moyenne une orchidectomie ou moins annuellement entre 2004 et 2006.

Si l'on veut procéder à une comparaison correcte entre les centres et permettre un retour d'information pertinent pour les centres, un ajustement du risque est nécessaire pour les indicateurs de résultat et peut être envisagé pour les indicateurs de processus. La faisabilité de la mesure des indicateurs étant l'objectif principal du projet, la nécessité d'un ajustement du risque n'a pas encore été évaluée. En conséquence, les résultats « bruts » présentés dans ce rapport ne peuvent pas être utilisés à des fins de comparaison ou de feedback en tant que tels, mais ils doivent faire partie du feedback individuel fourni aux hôpitaux.

CONCLUSIONS

- La mise en œuvre d'un ensemble d'indicateurs de qualité pour le cancer du testicule est réalisable à condition que certaines actions soient entreprises pour augmenter la mesurabilité de certains indicateurs de qualité. Cependant, la faible incidence du cancer du testicule constitue un facteur important qui doit être pris en considération au cas où l'opérationnalisation de cet ensemble d'indicateurs est envisagée (fréquence de rapportage et feedback, cumul de plusieurs années, etc.). La méthode la plus appropriée pour y parvenir, à savoir un ensemble complet d'indicateurs de qualité ou une analyse en profondeur des dossiers médicaux des patients décédés, doit encore être déterminée.
- Les bases de données couplées RBC-AIM suffisent pour l'évaluation de l'ensemble des indicateurs de qualité. La valeur ajoutée des données RCM est sujette à caution pour le présent ensemble d'indicateurs de qualité et se limite à des informations sur les orchidectomies. La mise à disposition d'un code de nomenclature plus adéquat pour les interventions chirurgicales pour cancer du testicule rendrait l'utilisation des données RCM moins utile encore.
- Cette analyse primaire montre un tableau mitigé de la qualité des soins pour les patients atteints d'un cancer du testicule. Si la survie est bonne, certains éléments indiquent une sur-utilisation de même qu'une sous-utilisation de certaines interventions.
- L'absence d'ajustement du risque (en particulier pour les indicateurs de résultat) dans le présent rapport ne permet pas une comparaison fiable entre les centres pour le moment. Néanmoins, l'analyse préliminaire suggère une variabilité considérable au niveau de la qualité des soins entre les centres, et souligne l'importance d'une mesure de la qualité et d'actions ultérieures visant à améliorer celle-ci, même dans un cancer rare comme celui du testicule. La fragmentation des soins et le faible nombre de patients atteints de cancer du testicule qui sont traités annuellement dans de nombreux centres suscite des interrogations à propos de l'organisation des soins pour ces patients et de la nécessité de centraliser ces soins dans un nombre limité de centres.

RECOMMANDATIONS^a

Sur la base des résultats du présent rapport, qui suggère une variabilité considérable au niveau de la qualité des soins pour les patients atteints de cancer du testicule, le suivi de la qualité des soins doit être envisagé. Toutefois, la méthode la plus appropriée pour y parvenir (un ensemble complet d'indicateurs de qualité ou une analyse en profondeur des dossiers médicaux des patients décédés), doit encore être déterminée. Avant de mettre en œuvre un ensemble d'indicateurs de qualité, les actions reprises ci-dessous sont recommandées.

Agenda de recherche :

- Pour chacun des indicateurs de qualité inclus, la nécessité d'un ajustement du risque doit être évaluée de manière approfondie;
- Pour chacun des indicateurs de qualité, des valeurs limites adéquates doivent être définies, en collaboration avec le Collège d'Oncologie.

Actions liées aux données:

1. Nomenclature:

- Les codes existants de la nomenclature relatifs à la chirurgie du testicule pour cause de cancer doivent être revus conformément aux normes de la pratique courante ;
- Les codes de la nomenclature pour la tomographie assistée par ordinateur (CT) et l'IRM doivent être spécifiques à une localisation anatomique.

2. Enregistrement des cancers

- L'usage correct de la 7^{ième} édition de la classification TNM et l'enregistrement complet des cTNM et des pTNM dans le registre du cancer doivent être encouragés.
- L'ajout de la « récurrence » à la liste actuelle de variables à enregistrement obligatoire au registre du cancer doit être envisagé, au moins pour un groupe de types de cancers sélectionnés.
- Les informations suivantes doivent être ajoutées dans le formulaire COM: dose et champ d'irradiation (volume cible clinique), enrôlement dans un essai clinique.

^a The KCE is the only responsible for the recommendations given to the public authorities

I INTRODUCTION

In 2004, the Belgian Section for Colorectal Surgery, a section of the Royal Belgian Society for Surgery, launched the PROCARE project (PROject on CAncer of the REctum) as a multidisciplinary, profession-driven and decentralized project (www.belgiancancerregistry.be). The main objective of this multidisciplinary project is to reduce diagnostic and therapeutic variability and to improve outcome in patients with rectal cancer by means of:

- standardization through guidelines (which were issued in 2007 ¹);
- implementation of these guidelines (workshops, meetings, training);
- quality assurance through registration and feedback.

In 2005, a multidisciplinary dataset was elaborated for registration in a rectal cancer specific database at the Belgian Cancer Registry (BCR). Registration started in October 2005. In order to allow individual feedback and national/international benchmarking, a quality indicator system was set up in 2008 ². At present, two rounds of feedback were already given to the participating centres.

The PROCARE project drew the attention of the Minister of Health. Indeed, in the National Cancer Plan 2008-2010 (http://www.laurette-onkelinx.be/articles_docs/32_initiatieven_N.pdf, accessed on November 16th 2010), initiative 9 aimed at the instauration of a 'personalised care program' for all new cancer patients. The development of these care programs, together with the follow-up of the quality of care, are the responsibilities of the College of Oncology. To allow an efficient realisation of this task, a structure is needed that allows a rapid development and update of clinical practice guidelines, the translation of these guidelines into concrete care programs, and the definition and implementation of quality criteria to follow up the quality of care. At present, the College of Oncology and the KCE already collaborate for the development of clinical practice guidelines ³⁻⁵. However, for the subsequent evaluation of the quality of care, no such collaboration exists.

As a preparation to set up a quality system for oncology in Belgium, the Minister asked the KCE to repeat the PROCARE project for a frequent cancer, i.e. breast cancer, and a rare cancer, i.e. testicular cancer. The main research questions are:

- Is it feasible to set up a quality indicator set for breast cancer and testicular cancer using the available administrative data? More specifically, the added value of the Minimal Clinical Dataset (MCD) and Minimal Financial Dataset (MFD) will be evaluated.
- Which methods/systems/structures are described in the literature to follow up the quality of care in oncology? This research question will be addressed in a subsequent report.

In a first phase, the national guidelines for both cancer types were updated and published earlier ^{6,7}. In a second phase, a quality indicator set was developed for both cancer types. In the present report, the development of a quality indicator set for testicular cancer will be discussed. The report on breast cancer will be published in parallel.

Based on the results from the 3 exercises (PROCARE included) and the experiences in other countries, recommendations will be formulated to set up a quality system for oncology. These will be discussed in a subsequent report to be published early 2011.

2 SELECTION PROCESS OF QUALITY INDICATORS

2.1 METHODOLOGY

2.1.1 Literature search

Both OVID Medline (see appendix for search strategy) and the grey literature were searched to identify published and validated quality indicators for testicular cancer. The following sources were considered to identify grey literature:

- National Quality Measures Clearinghouse: <http://qualitymeasures.ahrq.gov/>
- Agency for Healthcare Research and Quality: <http://www.ahrq.gov/>
- Joint Commission: <http://www.jointcommission.org/>
- Clinical Indicators Support Team: <http://www.indicators.scot.nhs.uk/>
- National Health Service: <http://www.nhs.uk/>

Furthermore, the CPGs identified during the development of the testicular cancer guideline were evaluated for included quality indicators.

The main searches were conducted in December 2009. An additional Medline search for 'pattern of care' studies was done in February 2010.

2.1.2 Addition of guideline-based quality indicators

The list of quality indicators resulting from the literature search was complemented by quality indicators derived from the recommendations of the testicular cancer guideline⁷. To this end, most individual recommendations were translated in at least one quality indicator.

2.1.3 Selection process

The long list of indicators, resulting from the literature search and addition of guideline-based indicators, was subjected to a formal assessment based on 4 criteria:

- Reliability: the extent to which the measure provides stable results across various populations and circumstances;
- Relevance: the extent to which important health conditions accounting for a major share of the burden of disease, the cost of care, or policymakers' priorities are reflected;
- Interpretability: the extent to which clear conclusions are possible;
- Actionability: the extent to which action can be taken by individuals, organised groups and public and private agencies to meaningfully address this aspect or problem.

Six expert (5 clinical experts and 1 KCE expert) independently scored each indicator on these 4 criteria using a scale from 1 (strongly disagree) to 5 (strongly agree). For each indicator and per criterion, the scores were summarized in a median score, minimum score, maximum score and the percentage of '4' and '5' scores. Finally, these summary scores were used during a plenary meeting to guide the final selection of indicators.

2.2 RESULTS

The Medline search yielded 24 (December 2009) and 338 (February 2010) hits respectively. Only one quality indicator (use of tumour markers) was identified⁸. The search in the grey literature did not identify additional indicators.

Based on the testicular cancer guideline, 31 additional quality indicators were proposed resulting in a long list of 32 indicators (Figure 1).

Figure 1. Selection process of testicular cancer quality indicators.

The evaluation scores of these 32 indicators are provided in appendix. During the plenary meeting and based on these scores, the list of indicators was reduced to a final selection of 12 quality indicators (Table 1). The most important criterion during this selection was relevance.

Table 1. Final selection of testicular cancer quality indicators.

Indicator	Type of indicator
Diagnosis and staging	
Proportion of patients with testicular cancer undergoing tumour marker assessment before any treatment	Process
Proportion of patients with testicular cancer undergoing contrast-enhanced Computed Tomography (CE-CT) or Magnetic Resonance Imaging (MRI) for primary staging	Process
Proportion of patients with testicular cancer discussed at the multidisciplinary team meeting	Process
Treatment	
Number of annually surgically treated patients with testicular cancer per centre	Process
Radiation dose and field in patients with testicular cancer treated with radiotherapy by stage	Process
Proportion of patients with stage I non-seminoma treated with active surveillance	Process
Proportion of patients receiving CE-CT or MRI for residual disease assessment at the end of systemic treatment	Process
Degree and duration of active surveillance in patients with stage I non-seminoma or seminoma	Process
Proportion of patients with relapsing testicular cancer after curative treatment that are included in a clinical trial	Process
Generic indicators	
Overall 5-year survival by stage	Outcome
Disease-specific 5-year survival by stage	Outcome
Disease-free 5-year survival by stage	Outcome

3 DATA SELECTION

Since this report is part of a larger project, that also includes the development of a quality indicator set for breast cancer, the data selection was done for both tumours at the same time. Therefore, the description of the data selection process also includes data on breast cancer.

3.1 PRIMARY SELECTION

From the BCR, the following records were selected:

- All breast and testicular cancers with incidence date between 01/01/2001 – 31/12/2006:
 - o ICD-10 breast: C50. (only invasive tumours)^a
 - o ICD-10 testis: C62. (only invasive tumours)
- For each selected patient, records related to other tumours (including in situ) were added

The primary selection resulted in 60 765 records, distributed amongst 54 173 patients. These data were sent to IMA and the Technical Cell for linkage (see Figure 2).^b

^a Breast carcinoma in situ (D05.) was not selected from the BCR data, because in the initial development of the project, only the quality of care for invasive tumours was considered. Because in a later phase also quality of care indicators (QCI) for ductal carcinoma in situ (DCIS) were considered, Minimal Clinical Data (MCD) were used in order to estimate these indicators.

^b The delivery of the BCR data to the IMA was done in two steps. First, the data of 2001-2004 were delivered; later on, the data of 2001-2006 were delivered. The present results all refer to the last data delivery.

Figure 2. Primary selection of breast and testicular cancer population.

3.2 ADDITIONAL SELECTION

From the MCD-MFD database (for the years 2002 – 2006), the selection of records was based on the following ICD-9-CM codes (see Figure 3):

Breast:

- 174.1 - 174.9: Malignant neoplasm of the breast
- 233.0: Carcinoma in situ of the breast

Testis:

- 86.0 and 86.9: Malignant neoplasm of the testis
- 36.4: Neoplasm with uncertain behavior of the testis

As an exhaustiveness check of the primary selection, the MCD records without an MFD-link and the MCD-MFD records without a counterpart in the linked BCR-IMA-MCD/MFD database were flagged and added to the research database.

Figure 3. Additional selection of breast cancer and testicular cancer patients using the MCD-MFD database as starting point.

3.3 EXPLORATION AND CHECK OF BCR DATA

Figure 4 gives an overview of the data selection, performed on the BCR dataset. The following steps were taken:

From the BCR dataset, selected as described above, the 845 records on non-melanoma skin tumours were omitted (due to an underregistration in the years 2001-2004)

Seventeen records were empty, because these patients, being foreigners, were omitted from the BCR database after the delivery of the data to the IMA. Furthermore, all records from patients who had any invasive tumour (including breast or testicular tumours) before 2001 were omitted, because previous invasive tumours may have significantly affected treatment of the breast or testicular cancer in the investigated period. In other words only patients with a first invasive breast or testicular carcinoma since 2001 were selected. In total, 2 803 records were deleted. Finally, 8 patients had a first invasive tumour between 2001 and 2006 that was not a breast or testicular tumour. These 8 were also omitted.

The resulting 57 092 records were split up into a file for testicular cancer and a file for breast cancer: 55 717 records concerned breast cancer patients, 1 375 records concerned testicular cancer patients. Furthermore, all records for men in the breast cancer database were deleted (471 records), resulting in a total of 55 246 records in the breast cancer database.

The next step was to obtain 1 record for each patient (Figure 5). The record that was chosen was the first reported invasive tumour within the topography investigated. If there was more than one tumour, the tumour with the highest pStage was chosen. If this selection did not result in one record per person, the tumour having a left laterality was chosen. The testis dataset with one record for each patient contained 1 337 patients, the breast dataset with one record for each patient contained 50 893 patients. In order to retain the information on multiple tumours, three variables were added to the dataset with one record per patient:

- The number of multiple tumours
- The number of multiple tumours within the same location as the primary tumour
- Whether multiple tumours were metachronous or synchronous. The definition of The American Society of Clinical Oncology (www.asco.org) was followed, considering synchronous tumours as those tumours that fall within the first three months after the incidence date of the first tumour (for the same laterality).

Figure 4. Data selection scheme.

Figure 5. Steps for obtaining one record per patient.

The last step was to remove 176 patients with a phyllodes tumour as primary tumour from the breast cancer database. Phyllodes tumours call for a different treatment than other breast carcinomas. The common treatment for phyllodes is wide local excision. Other than surgery, there is no cure for phyllodes, as chemotherapy and radiation therapy are not effective^{9, 10}.

The presence of double records was checked in the database (Figure 5). In the end, two records (of one patient) were still similar. Therefore, we consulted the original cancer registry database in order to check whether the records were indeed similar. Because this was the case, one of the records was omitted.

3.4 DATA LINKAGE

3.4.1 Linking BCR data to IMA data

The BCR data of the years 2001 to 2006 were linked to the IMA data from the same time interval:

1. From the 52 024 selected BCR records, 51 376 could be found in the IMAHEALTH database.
2. 648 patients were present in the BCR data, but not in the IMAHEALTH data, including the empty records mentioned earlier.

Figure 3. Overview of match between IMA and BCR data.

This means that 98.8% of the BCR data could be linked to IMA data. The remaining records were probably of patients who had no medical insurance provided by the health insurance companies or of whom the National Number (INSS) was not valid.

3.4.2 Linking BCR data to MCD data

For the years 2002 to 2006, all MCD databases were delivered. First, the proportion of patients from the primary selection that were available in the MCD database was calculated for each year per tumour (Table 2). Because of some unexpected time delays in this project, the delivery of data had to be performed in two phases. First, data from 2002 to 2004 were delivered to KCE, and the linkage of the three databases (MCD, BCR, IMA) could be performed. Then, in a second phase, MCD data were delivered for the years 2005 and 2006. Unfortunately, the linkage of these two years could not be performed on time to be included in this study. Consequently, all analyses including MCD data are based only on the years 2002 to 2004.

Table 2. Overview of match between BCR, IMA and MCD databases by year and tumour.

Tumour	Year	N BCR	N link with IMA (%)	N link with MCD (%)	N link with IMA and MCD (%)
Breast	2001	7764	7669 (98.8)	-	-
	2002	7751	7686 (99.2)	5909 (76.2)	5890 (76.0)
	2003	8525	8443 (99.0)	6567 (77.0)	6545 (76.8)
	2004	8330	8232 (98.8)	6069 (72.9)	6039 (72.5)
	2005	9091	8942 (98.4)	-	-
	2006	9256	9067 (98.0)	-	-
	Total	50717	50039		
Testis	2001	212	209 (98.6)	-	-
	2002	177	175 (98.9)	126 (71.2)	125 (70.6)
	2003	215	214 (99.5)	154 (71.6)	154 (71.6)
	2004	209	207 (99.0)	147 (70.3)	147 (70.3)
	2005	266	254 (95.5)	-	-
	2006	258	248 (96.1)	-	-
	Total	1337	1307		

In general, 18 972 patients could be linked between the BCR and the MCD database for the years 2002-2004 (75.3%). The number of patients that could be retrieved in both the IMA, BCR and MCD databases was 18 900 (75%).

This means that the linkage between the MCD data and the BCR data is much lower than between the BCR and the IMA data. A number of possible causes can be formulated:

There was certainly a problem with the creation of the patient ID's in the MCD database

Patients received different ID's over consecutive years in the MCD database

Only hospitalized patients appear in the MCD data. If a patient is not hospitalized or hospitalization dates from before 01/01/2002 then this patient is not recorded in the MCD database

4 DESCRIPTIVE STATISTICS

In total, the number of records for testicular cancer that were taken into account for the analyses was 1 375. The total number of unique patients in the final BCR dataset was 1 337. For the calculation of the descriptive statistics and the quality indicators, only the patients with a successful linkage between BCR and IMA data were considered ($n = 1\,307$).

4.1 DEMOGRAPHIC INFORMATION

Testicular cancer is more frequent in the age category 20-39 years (Figure 6). The youngest patient in the dataset was 0 years, the oldest patient was 95. The mean age of the sample was 34.5 years ($SD=12.6$).

Figure 6. Age distribution for testicular cancer ($n = 1\,307$).

4.2 TUMOUR CHARACTERISTICS

4.2.1 Solitary vs. multiple tumours

Most patients had a solitary tumour (97.1%). Thirty-eight patients (2.9%) had multiple tumours of which 18 were synchronous (incidence date of the second tumour within three months after the incidence date of the first tumour) and 20 were metachronous (incidence date of the second tumour more than three months after the incidence date of the first tumour). The most common multiple tumour locations were the prostate ($n = 8$), bone marrow ($n = 3$) and kidney ($n = 2$).

When only considering testicular tumours, 1291 patients (98.8%) had a unilateral tumour, while 16 patients (1.2%) had a bilateral testicular tumour (Table 3).

Table 3. Distribution of number of testicular tumours, 2001 – 2006 ($n = 1\,307$).

Number of testicular tumours	Frequency	%
Unilateral	1 291	98.8
Bilateral	16	1.2

4.2.2 Morphology

Seminomas were somewhat more frequent than non-seminomas (Table 4). Malignant teratomas are the most common non-seminoma tumours.

Table 4. Morphology of testicular tumours, 2001 – 2006 (n = 1 307).

Morphology		Frequency	%
Non-seminoma	Choriocarcinoma	33	2.5
	Malignant teratoma	269	20.6
	Embryonal carcinoma	225	17.2
	Other	84	6.4
Seminoma	Seminoma	696	53.3

4.2.3 pStage^c

The number of patients with unknown pStage was 394 (30.1%). More than 88% of the patients in whom the stage was known had pStage I (Figure 7). Figure 8 shows that seminomas tend to have lower pStage than non-seminomas.

Figure 7. pStage distribution for testicular cancer, 2001 – 2006.

Figure 8. Morphology by pStage for testicular cancer, 2001 – 2006.

^c Testicular cancer has only three pStages. The clinical stage is not presented here since the cT category is not used for staging testicular cancer. The small differences between the TNM version 5 (used until 2003) and version 6 (used from 2003 on) are neglected for this analysis: the two versions only differ in stage subcategories.

The stage distribution is comparable for all age categories, with stage I occurring most frequently, followed by stage II and III (Figure 9).

Figure 9. pStage distribution by age for testicular cancer, 2001 – 2006.

4.2.4 Incidence rates

In Table 5, the age-standardized incidence rate using a European standard (ESR)¹¹ is given for all available years. Note that data of the Walloon and Brussels region are not complete for the years 2001-2003. In 2006, Luxembourg had the highest ESR and Oost-Vlaanderen the lowest. Because testicular cancer is rather rare, a few more cases can cause a large increase in the incidence rate.

Table 5. Age-standardised incidence (ESR) per year and per region for testicular cancer.

PROVINCE	2001	2002	2003	2004	2005	2006
Antwerpen	3.05	2.61	2.75	2.95	4.81	5.64
Brussel-Bruxelles	-	-	-	2.63	4.36	3.81
Hainaut	-	-	-	4.34	6.21	4.51
Limburg	3.59	3.88	3.86	4.74	5.76	5.47
Liège	-	-	-	5.91	6.52	6.09
Luxembourg	-	-	-	2.43	7.23	7.83
Namur	-	-	-	4.54	4.49	7.16
Oost-Vlaanderen	3.74	3.57	4.04	3.78	3.72	3.04
Vlaams Brabant	2.89	3.79	2.96	3.36	3.93	6.19
Brabant Wallon	-	-	-	5.41	4.89	5.15
West-Vlaanderen	4.29	2.49	3.81	3.52	5.55	4.50

4.3 DIAGNOSIS AND STAGING

An overview of a selection of diagnostic techniques used in the workup of testicular cancer (between one month before and three months after incidence date) is given in Table 6. More than 70% of the patients underwent scrotal ultrasonography. The majority of the patients underwent a CT, although it is impossible to say of which anatomical location. Almost one fifth of the patients underwent a PET scan, of which most patients also underwent a CT and/or MRI.

Table 6. Overview of diagnostic techniques for testicular cancer, 2001 – 2006; BCR-IMA data only (n = 1 307).

Method	Frequency	Percent
Scrotal ultrasonography:		
• Specific codes ^d	927	70.9
• Non-specific codes ^e	76	5.8
CT	1 230	94.1
MRI	84	6.4
PET scan ^f	236	18.1
CT and/or MRI	1239	94.8
(CT and/or MRI) and PET scan	232	17.8

4.4 TREATMENT

A general overview of first treatment (time frame of 6 months after surgery) by pStage is provided in Table 7 and Table 8. Using the coupled BCR and IMA data only, 84.1% of all patients underwent orchidectomy for testicular cancer (Table 7). The proportion of surgically treated patients (orchidectomy) was slightly higher for pStage I (86.1%) and pStage II (86.3%) than for pStage III (76.4%). However, more pStage I patients only underwent orchidectomy compared to pStage II and III patients (18.1% vs. 0% vs. 14.7%).

The majority of the patients underwent adjuvant chemotherapy (41.5%), particularly in the case of pStage II disease (72.6%) and to a lesser extent in the case of pStage III disease (52.9%). An important proportion of the pStage I patients underwent adjuvant radiotherapy (at least 25.7%). Finally, 23.5% of the patients with pStage III disease only received chemotherapy.

Table 7. Treatment in general by stage, 2001 – 2006; BCR-IMA data only (n = 1 307).

Treatment	pStage				
	pI	pII	pIII	pX	All
Surgery only	146 (18.1%)	- (0%)	5 (14.7%)	102 (25.9%)	253 (19.4%)
Chemotherapy only	55 (6.8%)	9 (12.3%)	8 (23.5%)	45 (11.4%)	117 (9.0%)
Surgery + chemotherapy [§]	334 (41.4%)	53 (72.6%)	18 (52.9%)	137 (34.8%)	542 (41.5%)
Surgery + radiotherapy	207 (25.7%)	4 (5.5%)	- (0%)	55 (14.0%)	266 (20.4%)
Chemotherapy + surgery [§]	7 (0.9%)	6 (8.2%)	3 (8.8%)	20 (5.1%)	36 (2.8%)
Other / no treatment	57 (7.1%)	1 (1.4%)	0 (0%)	35 (8.9%)	93 (7.1%)
Total	806 (100%)	73 (100%)	34 (100%)	394 (100%)	1307 (100%)

[§] Some of these patients also received radiotherapy.

^d Nomenclature codes 460272, 460283, 469512 and 469523

^e Nomenclature codes 459793 and 459804

^f Nomenclature codes 442971, 442982, 442595 and 442606

When considering the coupled BCR, IMA and MCD data (only available for 417 patients and for the years 2002 – 2004), 89.9% of all patients had a specific code for orchidectomy (Table 8). The other results are more or less in line with those based on the BCR-IMA data, except for the rate of chemotherapy only (lower as calculated with the BCR-IMA-MCD data).

Table 8. Treatment in general by stage, 2002 – 2004; BCR, IMA and MCD data (n = 417).

Treatment	pStage				
	pl	pII	pIII	pX	All
Surgery only	63 (26.0%)	- (0%)	1 (7.7%)	44 (31.4%)	108 (25.9%)
Chemotherapy only	2 (0.8%)	1 (4.5%)	- (0%)	8 (5.7%)	11 (2.6%)
Surgery + chemotherapy [§]	104 (43.0%)	14 (63.6%)	9 (69.2%)	51 (36.4%)	178 (42.7%)
Surgery + radiotherapy	55 (22.7%)	1 (4.5%)	- (0%)	17 (12.1%)	73 (17.5%)
Chemotherapy + surgery [§]	2 (0.8%)	3 (13.6%)	2 (15.4%)	9 (6.4%)	16 (3.8%)
Other / no treatment	16 (6.6%)	3 (13.6%)	1 (7.7%)	11 (7.9%)	31 (7.4%)
Total	242 (100%)	22 (100%)	13 (100%)	140 (100%)	417 (100%)

[§] Some of these patients also received radiotherapy.

The analyses presented in Table 7 were repeated by morphology (Table 9 and Table 10). Slightly more patients with stage I non-seminoma were treated with orchidectomy only compared with stage I seminoma patients (21.1% vs. 16.0%). More importantly, while the majority of stage I seminoma patients was treated with orchidectomy and adjuvant radiotherapy (42.8%), the majority of stage I non-seminoma patients was treated with orchidectomy and adjuvant chemotherapy (64.8%). The latter was also the most important treatment for stage II (63.6%) and III (54.5%) seminoma patients and stage II (80.0%) and III (52.2%) non-seminoma patients.

Table 9. Treatment for seminoma by stage, 2001 – 2006; BCR-IMA data only (n = 696).

Treatment	pStage				
	pl	pII	pIII	pX	All
Surgery only	76 (16.0%)	- (0%)	1 (9.1%)	34 (19.1%)	111 (15.9%)
Chemotherapy only	25 (5.3%)	5 (15.2%)	2 (18.2%)	18 (10.1%)	50 (7.2%)
Surgery + chemotherapy [§]	119 (25.1%)	21 (63.6%)	6 (54.5%)	46 (25.8%)	192 (27.6%)
Surgery + radiotherapy	203 (42.8%)	4 (12.1%)	- (0%)	52 (29.2%)	259 (37.2%)
Chemotherapy + surgery [§]	4 (0.8%)	2 (6.1%)	2 (18.2%)	12 (6.7%)	20 (2.9%)
Other / no treatment	47 (9.9%)	1 (3.0%)	- (0.0%)	16 (9.0%)	64 (9.2%)
Total	474 (100%)	33 (100%)	11 (100%)	178 (100%)	696 (100%)

[§] Some of these patients also received radiotherapy.

Table 10. Treatment for non-seminoma by stage, 2001 – 2006; BCR-IMA data only (n = 611).

Treatment	pStage				
	pl	pII	pIII	pX	All
Surgery only	70 (21.1%)	- (0%)	4 (17.4%)	68 (31.5%)	144 (23.6%)
Chemotherapy only	30 (9.0%)	4 (10.0%)	6 (26.1%)	27 (12.5%)	67 (11.0%)
Surgery + chemotherapy [§]	215 (64.8%)	32 (80.0%)	12 (52.2%)	91 (42.1%)	350 (57.3%)
Surgery + radiotherapy	4 (1.2%)	- (0%)	- (0%)	3 (1.4%)	7 (1.1%)
Chemotherapy + surgery [§]	3 (0.9%)	4 (10.0%)	1 (4.3%)	8 (3.7%)	16 (2.6%)
Other / no treatment	10 (3.0%)	- (0%)	- (0%)	19 (8.8%)	27 (4.4%)
Total	332 (100%)	40 (100%)	23 (100%)	216 (100%)	611 (100%)

[§] Some of these patients also received radiotherapy.

In total, 735 patients (56.2%) received any type of chemotherapy (second-line included). From these, 586 (77.3%) received the BEP regimen (cisplatin + etoposide + bleomycine) (Table 11). Other frequently used regimens were EP (cisplatin + etoposide), carboplatin or VIP (cisplatin + ifosfamide + vinblastine). Regimens that are not recommended are not frequently used.

Table 11. Overview of chemotherapy products used for testicular cancer, 2001 – 2006; BCR-IMA data only (n = 1 307).

Product	Frequency	Percent
Cisplatin	616	47.1
Etoposide	612	46.8
Bleomycine	575	44.0
Carboplatin	131	10.0
Ifosfamide	84	6.4
Vinblastine	46	3.5
Cyclofosfamide	16	1.2
Doxorubicine	5	0.4
Any chemotherapy	735	56.2

4.5 HOSPITALIZATION

In the period 2002-2004, the majority of the patients with testicular cancer were hospitalized in APR-DRG 483 and 693 (Table 12).

Table 12. Overview of hospitalizations for testicular cancer by APR-DRG, 2002 – 2004 (n = 417).

APR-DRG	2002	2003	2004	Total
480: Major male pelvic procedures	-	2	-	2
483: Testes and scrotal procedures	36	58	50	144
484: Other male reproductive system & related procedures	1	2	-	3
500: Malignancy, male reproductive system	6	5	4	15
692: Radiotherapy	-	-	-	-
693: Chemotherapy	34	44	42	120
Other	45	40	48	133
Total	122	151	144	417

5 INDICATOR RESULTS

5.1 OVERALL MEASURABILITY OF THE SELECTED QUALITY INDICATORS

Of the 12 selected indicators, 5 were found to be measurable, 1 was partially measurable, and 2 indicators were measurable using a proxy indicator or proxy information (Table 13). The most important reason for being not measurable was the absence of administrative codes (N=2) or specific administrative codes (N=3). In the absence of national data on reasons for mortality disease-specific survival is not measurable as such. Therefore, relative survival was used as a proxy indicator.

Table 13. Measurability of testicular cancer quality indicators.

Quality indicator	Measurable	Comment
Diagnosis and staging		
TC1: Proportion of patients with testicular cancer undergoing tumour marker assessment before any treatment	Yes	
TC2: Proportion of patients with testicular cancer undergoing CE-CT or MRI for primary staging	No	No specific code available specifying the anatomical location for CT and MRI
TC3: Proportion of patients with testicular cancer discussed at the MDT meeting	Yes	
Treatment		
TC4: Number of annually surgically treated patients with testicular cancer per centre	Yes	Due to the absence of a nomenclature code for orchidectomy alone (without lymphadenectomy) other surgical codes needed to be taken into account (e.g. inguinal hernia repair)
TC5: Radiation dose and field in patients with testicular cancer treated with radiotherapy by stage	No	No administrative data on radiation dose and field
TC6: Proportion of patients with stage I non-seminoma treated with active surveillance	Yes	
TC7: Proportion of patients receiving CE-CT or MRI for residual disease assessment at the end of systemic treatment	No	No specific code available specifying the anatomical location for CT and MRI
TC8: Degree and duration of active surveillance in patients with stage I non-seminoma or seminoma	Partially	No specific code available specifying the anatomical location for CT and MRI
TC9: Proportion of patients with relapsing testicular cancer after curative treatment that are included in a clinical trial	No	No administrative data on inclusion in clinical trials
Generic indicators		
TC10: Overall 5-year survival by stage	Yes	
TC11: Disease-specific 5-year survival by stage	Yes	Calculable using relative survival
TC12: Disease-free 5-year survival by stage	Yes	Calculable using proxy for recurrence

5.2 INDICATOR RESULTS

For the graphical presentation of the variability between centres, it was decided to use funnel plots. A discussion on the choice of the methodology to calculate the funnel plots is presented in appendix. For this project it was decided to use the normal approximation for most funnel plots, but the Agresti-Coull interval for the funnel plots on survival.

5.2.1 Diagnosis and staging

According to the national guideline on testicular cancer ⁷, alphafetoprotein (AFP) and human chorionic gonadotrophin (HCG) should be measured preoperatively to distinguish between seminoma and non-seminoma and to guide postoperative management (expert opinion). Ideally, this measurement should be as close as possible to the first treatment. In the period 2001 – 2006, 73% of the treated patients underwent tumour marker assessment within 3 months of the first treatment, while 50% underwent the measurement within 2 weeks of the first treatment. A large variability was found across the different centres (Figure 10), with several centres attaining 100% for the period 2004 – 2006. Six outliers below the lower limit were identified for this period.

Figure 10. Proportion of treated patients with testicular cancer undergoing tumour marker assessment within 3 months of first treatment, analysis by centre (N=97), period 2004-2006 (BCR-IMA data only).

Primary staging for testicular cancer encompasses contrast-enhanced CT thorax, abdomen and pelvis, or, in particular cases, MRI abdomen/pelvis and CT thorax ⁷. In the period 2001 – 2006, almost 95% of all patients with testicular cancer underwent a CT and/or MRI within 1 month before and 3 months after incidence date. However, no information is available on the exact anatomic location of these imaging procedures.

Since testicular cancer is a rare cancer and asks for a specialized approach, a discussion of the therapeutic approach in a multidisciplinary setting, and based on the diagnostic and staging results, is necessary. Since February 2003, a specific nomenclature code became available for the billing of a multidisciplinary team meeting. Of all patients with an incidence date between February 1st 2003 and December 31st 2006, 58% were discussed during a multidisciplinary team meeting registered with the appropriate nomenclature code. Since the introduction of this code, its utilisation increased every year (Table 14).

Table 14. Proportion of patients with testicular cancer discussed during a multidisciplinary team meeting, BCR-IMA data, 2003 – 2006.

	Numerator	Denominator	Proportion
2003	88	198	44.4
2004	110	207	53.1
2005	165	254	65.0
2006	167	248	67.3
Total	530	907	58.4

However, the analysis per centre for the period 2004 – 2006 again shows a high variability among the centres (Figure 11). For a number of (small) centres no patient who was discussed at a MDT meeting could be identified using the IMA data. Importantly, the absence of a nomenclature code for a MDT meeting for a particular patient does not necessarily mean that no MDT was held. Some centres might not bill MDT meetings, and in turn, they do not appear in the IMA database. Moreover, these data do not allow an evaluation of the quality of this multidisciplinary discussion.

Figure 11. Proportion of patients with testicular cancer discussed during a multidisciplinary team meeting, analysis per centre (N=97), period 2004-2006 (BCR-IMA data only).

5.2.2 Treatment

5.2.2.1 Surgical volume

Using specific nomenclature codes for orchidectomy (available from the IMA database), only 71% of the patients with testicular cancer with an incidence date between 2001 and 2006 were found to be treated with orchidectomy. However, this number was considered an underestimation, and more detailed analyses showed that for a considerable number of patients (N=174) nomenclature codes for an inguinal hernia operation were registered between one month before and six months after testicular cancer diagnosis. Taking these codes into account (because of the time relation), 84% of the patients with testicular cancer were found to be treated with orchidectomy. Moreover, when also taking into account the hospital database (MCD), a total number of 90% was found to be treated with orchidectomy.

Between 2001 and 2003, 96 centres performed at least 1 orchidectomy for testicular cancer. Only 10 centres performed at least 10 orchidectomies during this time period, representing about one third of the surgically treated testicular cancer population. Between 2004 and 2006, 14 centres (out of a total of 97) performed at least 10 orchidectomies, representing about 40% of the surgically treated testicular cancer population during this time period (Figure 12).

Figure 12. Number of surgically treated patients with testicular cancer by centre, BCR-IMA data (2004-2006)*.

* Centres are sorted by total number of patients.

5.2.2.2 Radiotherapy

In total, about one third of the patients with stage I disease were treated with radiotherapy between 2001 and 2006. Of all stage II and III patients, about one fifth received radiotherapy. However, no information is available on the radiation dose and field used in these patients.

5.2.2.3 Active surveillance in stage I disease

Non-seminoma patients

Of all patients with known stage I non-seminoma diagnosed between 2001 and 2006 (N=332), 86% had a surgical nomenclature code and information on the vital status available. Of these, 24% were not treated with chemotherapy or radiotherapy within 6 months after surgical treatment, and were considered to be on active surveillance according to the initial definition of the indicator. In the period 2001-2006, the proportion of stage I non-seminoma patients on active surveillance remained quite stable, apart from a peak in 2003 (Table 15). However, data for 2006 need to be interpreted with caution, because nomenclature data after 2006 were not included in this study. The analysis per centre again showed a high variability (Figure 13).

Table 15. Proportion of patients with stage I non-seminoma on active surveillance, BCR-IMA data, 2001 – 2006.

	Numerator	Denominator	Proportion
2001	7	26	28.0
2002	6	36	17.1
2003	17	46	37.0
2004	11	51	22.0
2005	16	69	23.5
2006	12	58	20.0
Total	69	286	24.1

Figure 13. Proportion of patients with stage I non-seminoma on active surveillance, analysis per centre (N=67), period 2004-2006 (BCR-IMA data only)*.

* Several centres only treated 1 or 2 patients with stage I non-seminoma, resulting in overlapping point estimates for these centres.

Because of the somewhat surprisingly low number of stage I non-seminoma patients treated with active surveillance, the calculation of this indicator was repeated using an adapted definition. As many recurrences already occur within 6 months after orchidectomy, treatment started at least 3 months after orchidectomy was considered to be because of a recurrence in the adapted definition, while treatment started within 3 months after orchidectomy was considered to be adjuvant.

Using this adapted definition, the proportion of stage I non-seminoma patients treated with active surveillance was found to be about 29% for the period 2001-2006 (using BCR-IMA data only), which is only slightly higher than the original result.

Degree and duration of active surveillance

According to the national guidelines ⁷, active surveillance should encompass regular tumour marker assessment and imaging. Concerning imaging, the lack of specificity of the nomenclature codes for CT and MRI prevented the determination of this indicator (see also above). On the other hand, the degree and duration of tumour marker assessment after surgery could be determined.

Of all patients with known stage I disease (seminoma and non-seminoma) and with a surgical nomenclature code and information on vital status available (N=680), 21% were treated with active surveillance between 2001 and 2006. The mean number of tumour marker assessments by follow-up period fluctuated between 2001 and 2005. For seminomas, the mean number of tumour marker assessments during the first year after surgery approached the recommended number of 4 in 2002 (mean 3.89, SD 3.55), and started to increase since then (Table 16). For non-seminomas, the mean number of tumour marker assessments during the first year after surgery fluctuated between 10.5 and 14.6 during the time period 2001-2004 (Table 17). In 2005, it dropped to 8.9 (SD 8.4). For both tumour types, the mean number of tumour marker assessments decreased by year of postoperative follow-up (Table 16, Table 17, Figure 14 and Figure 15).

Table 16. Tumour marker assessment during active surveillance of patients with stage I seminoma, by year of surgery, BCR-IMA data only (2001-2006).

	Mean	SD	Median	25 th Pctl	75 th Pctl

Year of surgery: 2005 (N=19)					
1 st year after surgery	8.89	8.39	6	2	12

Figure 15. Number of tumour marker assessments per patient according to follow-up period, stage I non-seminoma, 2001-2005.

Using the adapted definition of recurrence and active surveillance as discussed above (3 months time delay after surgery), 27% of the patients with known stage I disease (seminoma and non-seminoma) and with a surgical nomenclature code and information on vital status available were considered to be on active surveillance between 2001 and 2006. With this adapted definition, the mean number of tumour marker assessments by follow-up period only slightly changed for seminomas (first year after surgery: between 3.86 in 2003 and 6.79 in 2005) (see tables in appendix). However, for non-seminomas clearly higher mean numbers were found in comparison with the first analysis (first year after surgery: between 9.60 in 2005 and 15.88 in 2001) and a decreasing trend became more clearly apparent (see tables in appendix).

5.2.3 Residual disease assessment after systemic treatment for stage II and III disease

In the time period 2001-2006, 107 patients were found to have known stage II or III testicular cancer. Of these, 91% were treated with chemotherapy. Restaging after chemotherapy is ideally performed with contrast-enhanced CT thorax, abdomen and pelvis or, in case of contra-indications, MRI abdomen-pelvis and CT thorax⁷. However, no specific nomenclature codes were available for CT thorax or abdomen or pelvis, or MRI abdomen-pelvis. Moreover, the identification of contrast-enhanced CT was difficult, since the available codes for contrast were not consistently used (the combination of the nomenclature codes for CT and the CNK codes for contrast resulted in zero records). As a result, this indicator could not be assessed.

Nevertheless, some results can be calculated using the available administrative data. Of the stage II/III patients treated with chemotherapy, 54% underwent a CT (of the neck and/or thorax and/or abdomen) and/or a MRI (of the neck and/or thorax and/or abdomen) within 6 months after the end of the chemotherapy.

5.2.4 Survival

Three measures of survival were calculated: overall survival, relative survival (as a proxy for disease-specific survival) and disease-free survival.

For the entire population, survival measures are presented by stage in Table 18. Especially for stage I and II, 5-year survival is high (97% and 95% respectively). For stage III disease, 5-year relative survival still is 76%.

Table 18. Survival for testicular cancer by stage, 2001-2006.

	pStage		
	I	II	III
5-year overall survival	0.97	0.95	0.71
5-year relative survival	0.97	0.95	0.76

No obvious differences in survival were found between seminomas and non-seminomas (5-year observed survival 94% vs. 93%).

Figure 16. Kaplan-Meier curve for observed survival, seminoma vs. non-seminoma, 2001-2006.

Overall, 5-year survival slightly increased between 2001 and 2004 (Table 19).

Table 19. Evolution of survival for testicular cancer, 2001-2004.

	2001	2002	2003	2004
5-year overall survival	0.91	0.93	0.95	0.94
5-year relative survival	0.92	0.94	0.95	-

The analysis by centre shows a high proportion of centres achieving a 5-year survival of 100% for pStage I patients (Figure 17). Nevertheless, some centres clearly achieved worse survival rates. The number of patients and events in pStage II and III were too small for the analysis by centre.

Figure 17. Observed 5-year survival of stage I disease by centre, 2001-2006.

For the calculation of the disease-free survival, in the absence of a specific code, recurrence was originally defined as the event of receiving new treatment at least 6 months after the first treatment. Using this definition, the 5-year disease-free survival for the entire cohort was estimated to be 96% (Table 20).

Table 20. Disease-free survival for testicular cancer, 2001-2004.

	1 year	2 year	3 year	4 year	5 year
Disease-free survival*	0.99	0.98	0.98	0.97	0.96

* pX stage included.

The degree of variability across centres was rather limited, with many centres achieving a 5-year disease-free survival of 100% (Figure 18). Still, for some smaller centres, lower disease-free survival rates were detected.

Figure 18. Disease-free 5-year survival for testicular cancer by centre, 2001-2004.

Using the adapted definition as discussed above, the 5-year disease-free survival slightly decreased to 94%. However, the variability across the centres largely remained the same.

6 DISCUSSION

6.1 INDICATOR RESULTS

6.1.1 National level

Results show a mixed picture

The descriptive statistics and selected quality indicators show a mixed picture of the quality of care for patients with testicular cancer in Belgium in the period 2001-2006. Positive evolutions are found for the pre-treatment assessment of tumour markers and the multidisciplinary team meeting (Table 21). Above this, the survival of testicular cancer patients is slightly improving since 2001. On the other hand, the proportion of stage I non-seminoma patients treated with active surveillance seems to be too low and still declining. Furthermore, the use of tumour marker assessment during active surveillance is increasing for seminomas (to a level above the recommended number), but decreasing for non-seminomas (to a level below the recommended number).

Importantly, for the interpretation of these evolutions, one should take into account the fact that a selection bias is present for the years 2001-2003 (and even 2004). In that period, mostly university hospitals participated at the cancer registration. Also, the Walloon and Brussels Capital Region had an incomplete coverage at that time. Progressively, more and more smaller centres started to participate at the cancer registration, possibly resulting in a 'diluting' effect for some indicators (e.g. active surveillance). It would therefore be interesting to evaluate in how far each indicator remains stable over time on the individual centre level.

Table 21. Evolution of measurable quality indicators between 2001 and 2006.

Indicator	Result 2001	Result 2006
Proportion of patients with testicular cancer undergoing tumour marker assessment before any treatment	72.3%	80.6%
Proportion of patients with testicular cancer discussed at the MDT meeting	53.1% (2004 result)	67.3%
Proportion of surgically treated patients with testicular cancer	81.3%	81.0%
Proportion of patients with stage I non-seminoma treated with active surveillance	28.0%	20.0%
Mean number of tumour marker assessments in the first year after surgery during active surveillance of patients with:		(2005 result)
• Seminoma	5.5	6.5
• Non-seminoma	10.5	8.9
Observed 5-year survival	91%	94% (2004 result)
Relative 5-year survival	92%	95% (2003 result)

Survival is slightly increasing

Between 2001 and 2003 the relative survival for the entire Belgian cohort rose from 92% to 95% (Table 21). The survival rates found in the present report are in line with the rates reported for other countries (Table 22). However, where some reports described a difference in 5-year relative survival between seminomas and non-seminomas (France: 100% and 91% respectively; Japan: 96% and 82% respectively)^{12, 13}, no such difference was found for the Belgian cohort.

Table 22. Relative survival in foreign cohorts.

Year of diagnosis	Relative 5-year survival
The Netherlands ¹⁴	
1993-1997	94%
1998-2002	91%
2003	94%
France ¹²	
1994-1999	97%
Norway ¹⁵	
1994-1998	91%
1999-2003	92%
Sweden ¹⁵	
1994-1998	92%
1999-2003	94%
US ¹²	
1999-2005	95%
Japan ¹³	
1993-1999	91%

During the expert meeting for the present report, it was suggested to present the survival by prognostic risk group. However, information on risk profile is not yet available at the BCR. If the 7th edition of the TNM classification ¹⁶ would be used correctly with complete registration at the BCR (including the S category for tumour markers), this risk stratification would be possible.

Use of tumour markers is moderate to good

In testicular cancer, the use of tumour markers is an important component of care as they impact the subsequent treatment and outcome. The proportion of patients with testicular cancer undergoing pre-treatment tumour marker assessment rose from 72% in 2001 to about 81% in 2006.

In a US study using SEER data of 4 742 testicular cancer cases (1998-2002), the proportion of patients undergoing tumour marker assessment (AFP and HCG) was 45%⁸, which is considerably lower than in the present study. In the US study, tumour marker use also varied substantially according to the SEER site.

Multidisciplinary discussion is gaining interest

The increase of the proportion of patients with testicular cancer discussed at the MDT meeting is not surprising, since the nomenclature code was only created early 2003. However, in comparison to other tumour types, the proportion is rather low. For breast cancer for example, the proportion was already about 80% in 2006 (Stordeur et al. 2010, in press), while in the year the nomenclature code was implemented (2003), the proportion was already 65% for rectal cancer (cT3-4, cN+ and/or cStage IV) ². A possible explanation is that not all MDT meetings are billed. A subanalysis by stage or age group might have revealed other explanations, but was not considered necessary for the present report.

Rates of orchidectomy seem to be low

Using the linked BCR-IMA data a surprisingly low rate of orchidectomies (71%) was found when using specific nomenclature codes (Table 23). Taking into account nomenclature codes for inguinal hernia repair, as suggested by some experts, the rate rose to 84%. When considering also the MCD codes, a rate of 90% was found. However, even this result was considered to be too low, as almost all patients with testicular cancer should undergo orchidectomy. Osswald et al. for example found an orchidectomy rate of above 99% in 702 testicular cancer cases ¹⁷.

Possible explanations raised by the experts for this low orchidectomy rate are the use of a wrong or even no nomenclature code. Indeed, as no specific nomenclature code exists for a 'simple' radical orchidectomy without lymphadenectomy, some experts prefer not to bill the intervention. Note that also aspecific nomenclature codes exist for retroperitoneal lymph node dissection. These codes were not considered in this report.

Table 23. Rates of orchidectomy (2001-2006) according to used administrative codes.

Administrative code	Rate 2001 - 2006
Radical orchidectomy for primary testicular tumour with inguinal and/or iliac and/or lumbar lymphadenectomy (nomenclature codes 261111, 261122) OR Bilateral orchidectomy (nomenclature codes 261096, 261100)	71%
Above codes OR Surgical treatment of inguinal hernia without bowel resection (nomenclature codes 241113, 241124) OR Surgical treatment of hernia, irrespective of used technique (nomenclature codes 241161, 241150)	84%
Above codes AND/OR Unilateral orchidectomy (ICD-9-CM 62.3) OR Bilateral orchidectomy (62.4) OR Removal of both testes at same operative episode (62.41) OR Removal of remaining testis (62.42)	90%

Rates of active surveillance are low

The rates of active surveillance were found to be low, even when using a more 'liberate' definition of active surveillance (29% for stage I non-seminomas, 27% for stage I seminomas). For stage I seminomas, this can be explained by the fact that there is really a choice between active surveillance, single-dose carboplatin and radiotherapy⁷. However, for stage I non-seminomas, primary surveillance is recommended for patients *without vascular or lymphatic invasion and without a predominant embryonal component*⁷. Unfortunately, these characteristics could not be analysed in the present project to explain the low rate of active surveillance.

In comparison, Osswald et al. found a rate of active surveillance of 41% for localized non-seminomas and 12% for localized seminomas¹⁷.

No information on number of patients included in clinical trials

No exact data are available on the number of patients with testicular cancer that are included in a clinical trial. According to the consulted experts, mainly the larger academic centres include patients in clinical trials, representing about 30-40% of all patients with testicular cancer at a maximum.

Recently, Deloitte analysed the number of clinical trials in Belgium that are registered at the Federal Agency for Medicines and Health Products¹⁸. About 24% of the newly started clinical trials between 2006 and the first semester of 2009 (n = 1943) were in the domain of antineoplastic and immunomodulating agents. However, no information was presented by tumour type.

6.1.2 Comparison between centres

The results available from the descriptive statistics and measurable quality indicators show a considerable degree of variability across the different centres. This variability is most prominent for the included process indicators, although some variation is also present in terms of survival.

Striking is the dispersion of care for patients with testicular cancer. Of all orchidectomies for testicular cancer between 2004 and 2006, 40% was performed in 14 centres, while the remaining 60% was performed in 83 centres. More than one third of the centres treating patients with testicular cancer performed a mean of one orchidectomy or less per year between 2004 and 2006. This dispersion of care and the resulting low annual number of patients with testicular cancer in many centres renders comparison between centres difficult. It also raises questions about the organisation of care for these patients and the need to centralise this care in a limited number of centres. In fact, in 2011 the KCE will start a project to investigate the optimal organisation of care for rare cancers, including testicular cancer.

In at least one (Japanese) study¹³ a relation between surgical volume and outcome was suggested. Using data of 326 patients with testicular germ cell cancer diagnosed between 1993 and 1999, a significant association was found between survival and hospital procedure volume after adjustment for clinical stage, age and histology (adjusted hazard ratio for hospitals with at least 25 procedures compared to hospitals with 7 or less procedures between 1993 and 1999: 0.111, 95%CI 0.025-0.495). Because this was not foreseen in the present project, a volume-outcome analysis was not performed with Belgian data. Nevertheless, such analysis would probably prove to be very interesting.

For the correct comparison between centres and to allow a meaningful feedback to the centres, risk adjustment is probably necessary for outcome indicators, and can be considered for process indicators. Since feasibility was the main scope of the present project, the need for risk adjustment was not yet evaluated. Therefore, the 'raw' results presented in this report should not be used for comparison and feedback as such. Nevertheless, they should be part of the individual feedback given to the hospitals. Before the included quality indicators are implemented, the exercise of risk adjustment should be done first, in particular because the added value of risk-adjustment is unsure for rare cancers. Table 24 provides an overview of possible factors to be adjusted for when calculating the quality indicators, although it should be noted that some of these risk factors are not (yet) available from the administrative databases. Importantly, to allow a correct adjustment by pStage, the current rate of known pStages (70% between 2001 and 2006) is insufficient and every effort should be made to increase this rate.

Interestingly, the KCE is currently performing a study on methodologies for risk-adjustment using the PROCARE data. The results of that study can probably be used for more general recommendations that are of interest for other cancer types too.

Table 24. Possible risk factors to adjust for per indicator.

Quality indicator	Risk factors
Diagnosis and staging	
TC1: Proportion of patients with testicular cancer undergoing tumour marker assessment before any treatment	Age, stage, morphology
TC2: Proportion of patients with testicular cancer undergoing CE-CT or MRI for primary staging	Age, stage, morphology
TC3: Proportion of patients with testicular cancer discussed at the MDT meeting	Age, stage, morphology
Treatment	
TC4: Number of annually surgically treated patients with testicular cancer per centre	Age, stage, morphology
TC5: Radiation dose and field in patients with testicular cancer treated with radiotherapy by stage	Age, morphology, prognostic group
TC6: Proportion of patients with stage I non-seminoma treated with active surveillance	Age, prognostic group
TC7: Proportion of patients receiving CE-CT or MRI for residual disease assessment at the end of systemic treatment	Age, stage, morphology, prognostic group
TC8: Degree and duration of active surveillance in patients with stage I non-seminoma or seminoma	Age
TC9: Proportion of patients with relapsing testicular cancer after curative treatment that are included in a clinical trial	Age, stage, morphology, prognostic group
Generic indicators	
TC10: Overall 5-year survival by stage	Age, morphology, prognostic group
TC11: Disease-specific 5-year survival by stage	Age, morphology, prognostic group
TC12: Disease-free 5-year survival by stage	Age, morphology, prognostic group

6.2 INDICATOR MEASURABILITY AND INTERPRETABILITY

Of the 12 included quality indicators, 4 were clearly not measurable, 1 was partially measurable, while 2 others were only measurable using proxy information (Table 13). It is well known that the current nomenclature and hospital data are not always suitable for quality measurement, simply because they were not created for this cause. Nevertheless, it is also clear that the nomenclature is not always adapted to the current state-of-the-art medicine. For the present report, this was clearly the case for orchidectomy (see discussion above). Furthermore, as in other reports², the absence of nomenclature codes for CT and MRI (and to a lesser extent ultrasonography) with unambiguous specification of the anatomic location is an important hinder to evaluate diagnostic, staging and follow-up procedures. A possible solution would be to link the nomenclature to the diagnosis.

Even when the available administrative data allowed the measurement of quality indicators or descriptive statistics, the results were sometimes questionable. An example is the number of pStage III patients exclusively treated with surgery (N=5 between 2001 and 2006), which should be zero (and in reality probably is zero). Possible explanations for this high number are absence of billing, errors in the administrative databases, or inclusion of these patients in clinical trials (rendering some of the therapeutic interventions untraceable). These considerations should be taken into account when interpreting the results of all quality indicators measured with these administrative data. Nevertheless, it should be stressed that results of quality indicators are only indicative and, if aberrant, should lead to more in depth analysis.

Besides the data quality, timeliness of information is another important aspect influencing the interpretation of results. For the 3 consulted administrative databases, a time delay of 2-3 years is achievable. Furthermore, the linkage and analysis of data also takes several months. For the present study, data from 2001 – 2006 were used, and therefore the results should be interpreted taking into account the guidelines applicable for that time period. For cancer types with a rapidly evolving evidence base, this can be a true problem. Ideally, the delay between the incidence date and the availability of data must be kept as short as possible, with a maximum of 2 years.

Being an important outcome in oncology, (local or distant) recurrence or disease-free survival is often considered for inclusion in quality indicator sets. However, in Belgium, recurrence is not registered. For the present report, this was solved by using a proxy for recurrence, i.e. the instauration of new treatment at least 3-6 months after the first treatment. However, using this definition, patients with a real recurrence within 3-6 months after the first treatment are not counted as having a recurrence. Furthermore, for other tumour types, such as breast cancer or rectal cancer, this solution would not be adequate. Therefore, adding 'recurrence' to the current list of variables with obligatory registration at the cancer registry should be considered, at least for a selected group of cancer types (including the most frequent cancer types and some less frequent cancer types with high impact). In a first phase, this could be done in the context of a well-defined (prospective) registration protocol, as is done for PROCARE².

Another problem is the absence of national data on causes of mortality, hampering the calculation of the disease-specific survival. As in other studies (see above), this was solved by using relative survival as a proxy. However, in the near future, national data should again be available. The upcoming European regulation in this domain should enhance the capacity to have data on causes of mortality with a delay of less than a 2-year period.

One of the outcomes of the present report was to evaluate the added value of MCD data to increase the measurability of the included indicators. However, many technical problems led to an incomplete linkage of MCD data to linked BCR-IMA data. Eventually, linked BCR-IMA-MCD data were only available for the years 2002-2004 and for a limited number of cases. MCD data helped improving the measurability of indicators involving surgical treatment (surgical volume, proportion of stage I patients treated with active surveillance). If there would be a more appropriate nomenclature code for orchidectomy, the added value of the MCD data would become questionable. The added value of MCD for other indicators was not demonstrated. Also, because of the above mentioned technical problems, the MCD data could not help to assess exhaustivity of the BCR data.

Based on the above discussion, actions are suggested to increase the measurability of some quality indicators (Table 25). Some suggested actions have an impact on several indicators, and are not always repeated. Apart from these suggestions, target rates need to be determined for each individual indicator.

Table 25. Suggested actions to increase measurability of testicular cancer quality indicators.

Quality indicator	Action
Diagnosis and staging	
TC1: Proportion of patients with testicular cancer undergoing tumour marker assessment before any treatment	-
TC2: Proportion of patients with testicular cancer undergoing CE-CT or MRI for primary staging	Create nomenclature codes for CT and MRI with unambiguous specification of the anatomic location, e.g. separate codes for CT thorax, CT abdomen and CT pelvis (same applies to MRI)
TC3: Proportion of patients with testicular cancer discussed at the MDT meeting	-
Treatment	
TC4: Number of annually surgically treated patients with testicular cancer per centre	Create specific nomenclature codes for orchidectomy reflecting the current state-of-the-art (e.g. separate codes for (1) radical orchidectomy for testicular cancer and for (2) retroperitoneal lymph node dissection for testicular cancer, instead of the existing nomenclature code for orchidectomy)
TC5: Radiation dose and field in patients with testicular cancer treated with radiotherapy by stage	Include information in MDT form
TC6: Proportion of patients with stage I non-seminoma treated with active surveillance	Oblige registration of recurrence? If using the proxy definition of the present report, use 3 months instead of 6 months as time delay between surgery and new treatment
TC7: Proportion of patients receiving CE-CT or MRI for residual disease assessment at the end of systemic treatment	Create nomenclature codes for CT and MRI with unambiguous specification of the anatomic location (see above)
TC8: Degree and duration of active surveillance in patients with stage I non-seminoma or seminoma	Create nomenclature codes for CT and MRI with unambiguous specification of the anatomic location (see above)
TC9: Proportion of patients with relapsing testicular cancer after curative treatment that are included in a clinical trial	Include information in MDT form
Generic indicators	
TC10: Overall 5-year survival by stage	Collect data on risk groups to allow presentation of survival by risk group
TC11: Disease-specific 5-year survival by stage	Collect national data on causes of mortality
TC12: Disease-free 5-year survival by stage	Oblige registration of recurrence?

6.3 DESIRABILITY OF A QUALITY INDICATOR SET FOR TESTICULAR CANCER

As discussed above, this preliminary analysis at least suggests a considerable variability in the quality of care for patients with testicular cancer, underpinning the importance of quality measurement and subsequent quality improvement actions, even for a rare cancer such as testicular cancer. However, several factors need to be taken into account when the operationalisation of this indicator set is considered.

First, the survival data show that the prognosis of most patients with testicular cancer is already good with little room for improvement. Therefore, it may be more useful to focus on results suggesting overtreatment (e.g. the low number of patients treated with active surveillance) and on patients that died during the follow-up period. About 80 patients with testicular cancer died within 5 years after diagnosis in this cohort, which is a manageable number for a more in depth analysis of the medical file. Such an analysis of a limited number of medical files may be a more efficient alternative to the measurement of an entire quality indicator set.

Furthermore, being a rare cancer, the impact of testicular cancer on public health is very limited. Other cancer types, such as breast cancer, have a much higher impact and probably should and will receive priority. Nevertheless, even patients with a rare cancer deserve care of the best quality.

Finally, implementation of a quality indicator set only has sense when it is embedded in a quality improvement cycle. When abnormal or unexpected results are found, indicators are indicative of a potential problem and deserve a closer look. If real problems are encountered, they should lead to quality improvement actions and, subsequently, a re-evaluation after a certain time period. Although actionability was one of the selection criteria for the quality indicators, it is clear that some indicators are more actionable than others.

6.4 CONCLUSIONS

The following conclusions can be drawn from the present report:

- It is feasible to implement a quality indicator set for testicular cancer if some actions are undertaken to increase the measurability of the quality indicators. However, the low incidence of testicular cancer is an important factor to be taken into account when operationalisation (frequency of reporting and feedback, accumulation of several years, etc.) of this indicator set is considered. The most appropriate method, i.e. the implementation of an entire quality indicator set or the use of a possibly more efficient alternative such as an in depth analysis of the medical files of the deceased patients, still needs to be determined.
- The linked BCR-IMA data were found to be sufficient for the measurement of the present quality indicator set. The added value of MCD data is questionable and is limited to information on orchidectomies. The availability of a more appropriate nomenclature code for surgical interventions related to testicular cancer would render the information from the MCD data even more redundant.
- This preliminary analysis shows a mixed picture of the quality of care for testicular cancer patients. Survival is good, but there are indications of over- and underuse of certain interventions.
- The absence of risk-adjustment in the present report (especially for outcome indicators) does not allow a reliable comparison between centres at present. Nevertheless, the preliminary analysis at least suggests a considerable variability in quality of care between centres, underpinning the importance of quality measurement and subsequent quality improvement actions, even for a rare cancer such as testicular cancer. The dispersion of care and the resulting low annual number of patients with testicular cancer in many centres raises questions about the organisation of care for these patients and the need to centralise this care in a limited number of centres.

7.3 CONSTRUCTION OF AN ALGORITHM TO ATTRIBUTE A PATIENT TO A HOSPITAL BASED ON IMA ADMINISTRATIVE DATA

7.3.1 Introduction

Description of the problem: how to identify the “main centre” for each patient, when the available data arise from three databases, each having different ways to identify the hospital?

This document will address different questions:

1. How to deal with hospital merging?
2. How to identify centre in IMA data?
3. How to identify centre in MCD data?
4. Is there consistency between approaches to identify centres?
5. What's the added value of MCD data compared to IMA data to identify centre?
6. How to construct a valid algorithm?

For this project, there are three sources of data:

1. **BCR dataset** (initial selection): there is no centre identifier (at least for this project)

Unique key: patient – type of tumour – incidence date

2. **IMA Health dataset** (linked to BCR data): the centre is identified by a nomenclature code (if the MDT meeting and surgery are performed at two different places, the two centres are identified in the database)
Unique key: patient (after regularizations) – nomenclature code – prestation date

There are two variables which identify the institution in the IMA.Health dataset: The variable **SS00075** indicates where the patient was hospitalized, but is often left blank, so does not provide reliable information. The variable **SS00085** is the location where the medical act (nomenclature code) was performed. This variable specifies the centre (hospital) in addition to the service (or lab centre). It requires a specific recoding by the data manager, who will group together all different codes/ identifiers from the same hospital (see annex I).

3. **MCD dataset** (linked to BCR data): the centre is the one where the patient was hospitalized.

Unique key: patient- hospitalization (isnr).

The variable **HOSPIDR_NEW** (in the MCD.STAYHOSP dataset) is the hospital where the patient was hospitalized. This variable also requires a recoding by the data manager, so that the same hospital is recoded by the same identifier in the IMA health dataset and in the MCD dataset

7.3.2 Methods

7.3.2.1 How to deal with hospital merging?

The table HOSPITAL (see a selection below) makes the link between the recoded ss00085 (ss00085r) and the hospital. Merges between hospitals are indicated by the “change” and “change_date” variables. This table has been created by the data manager, and is based on the 2009 situation. For the purpose of this project, all centres were merged retrospectively (in the past). For instance, centre A and centre B which merged into centre C in 2005 were labelled centre C during the whole study period (2001-2006). Hospitals which merged after the study period (2007-2009) were also retrospectively merged.

Table 26. Reference table for the link between the variable SS00085 and the hospital code in IMA data.

SS75or85r	hospidr	hospidr_new	change_date	change	hosp_type
030479B	FF007				HOP-ZKH
03328B5	96361				HOP-ZKH
03341CB	7343B				HOP-ZKH
0341907	8DFB1	53359	01JAN2000	FUSION	HOP-ZKH

7.3.2.2 How to select centre in the IMA data?

There are several possibilities to select centre in the IMA data

- From the **MDT meetings** (see nomenclature codes in the technical document)
- From the **surgery** (see nomenclature codes in the technical document)
- From the **chemotherapy** (see nomenclature codes in the technical document)
- From the **lump sums for hospital admission and per diem price** (see nomenclature codes in Table 27)
- Hormonal therapy is not considered here as mainly given in an ambulatory setting.

Table 27. Nomenclature codes for lump sums (per diem) in IMA data.

Code	Start Date	NL	FR
760001	01/01/1993	Heelkundige aandoeningen - Observatie en behandeling : Niet-universitaire inrichtingen	Affections chirurgicales - Observations et traitement : Etablissements non-universitaires
760060	01/01/1993	Heelkundige aandoeningen - Observatie en behandeling : Gemengde inrichtingen	Affections chirurgicales - Observations et traitement : Etablissements mixtes
760126	01/01/1993	Heelkundige aandoeningen - Observatie en behandeling : Universitaire inrichtingen	Affections chirurgicales - Observations et traitement : Etablissements universitaires
768003	7/01/2005	Ziekenhuisverpleging - variabel gedeelte op basis van ingediende facturen : Acute ziekenhuizen - bedrag per opname.	Hospitalisation - partie variable sur base des factures introduites : Hôpitaux aigus - forfait par admission.
768025	7/01/2002	Ziekenhuisverpleging - variabel gedeelte op basis van ingediende facturen : acute ziekenhuizen - bedrag per dag	Hospitalisation - partie variable sur base des factures introduites : hôpitaux aigus - forfait par jour

However, for each of these codes, time limits have to be set with regard to the incidence date of the cancer (see Table 28). This is to ensure that the treatment relates to the selected cancer. In general, a time limit of 6 months before or after the incidence date is chosen. A smaller time window has been chosen for the lump sums, because these are not specific for cancer (these codes are valid for any hospitalization, cancer or non cancer related).

These limits are cancer specific and should be reviewed by experts for each type of cancer.

Table 28. Time windows applied to nomenclature codes in IMA (reference date: incidence date from BCR).

Category	Source of data	Time between nomenclature code date and incidence date (after)	Time between nomenclature code date and incidence date (before)
MDT meetings	IMA	6 months (180 days)	1 month (30 days)
Surgery	IMA	6 months (180 days)	1 month (30 days)
Chemotherapy	IMA	6 months (180 days)	6 months (180 days)
Lump sum any hospitalization	IMA	1 month (30 days)	1 month (30 days)

The last step is to check that the centre can be uniquely identified for each category. For instance, for patients having two MDT meetings in two different centres within the 6 months period after incidence date, the centre cannot be uniquely identified on this criterion.

The consistency between different approaches should be described.

7.3.2.3 How to select centre in the MCD data?

First, only hospitalizations with regard to the studied cancer have to be retained. One possibility is to select all the relevant APR-DRGs, or all the relevant stays with the appropriate primary diagnosis, but a first broad and easier selection can be done at the level of the Major Disease Classification (MDC). For testis, the relevant MCD is MCD 12 “Diseases and Disorders of the Male Reproductive Systems”, which contains the APR-DRGs reported in Table 29.

Table 29. APR-DRGs in MDC 12 “Diseases and Disorders of the Male Reproductive Systems”.

APR-DRG	M/P	NL	FR	ENG
480	P	MAJEURE INGREPEN OP DE PELVIS BIJ DE MAN	INTERVENTIONS MAJEURE SUR PETIT BASSIN, SEXE MASCULIN	MAJOR MALE PELVIC PROCEDURES
481	P	INGREPEN OP DE PENIS	CHIRURGIE DU PENIS	PENIS PROCEDURES
482	P	TRANSURETHRALE PROSTATECTOMIE	PROSTATECTOMIE TRANSURETRALE	TRANSURETHRAL PROSTATECTOMY
483	P	INGREPEN OP DE TESTES	INTERVENTIONS SUR LES TESTICULES	TESTES PROCEDURES
484	P	ANDERE INGREPEN OP HET MANNELIJK VOORTPLANTINGSSTELSEL	AUTRES INTERVENTIONS SUR LE SYSTEME GENITAL MASCULIN	OTHER MALE REPRODUCTIVE SYSTEM PROCEDURES
500	M	MALIGNE AANDOENINGEN VAN HET MANNELIJK VOORTPLANTINGSSTELSEL	AFFECTIONS MALIGNES DU SYSTEME GENITAL MASCULIN	MALIGNANCY, MALE REPRODUCTIVE SYSTEM
501	M	ANDERE AANDOENINGEN, BEHALVE MALIGNE, VAN HET MANNELIJK VOORTPLANTINGSSTELSEL	AUTRES AFFECTIONS DU SYSTEME GENITAL MASCULIN SAUF AFFECTIONS MALIGNES	MALE REPRODUCTIVE SYSTEM DIAGNOSES EXCEPT MALIGNANCY

Another relevant MDC for all cancers is the MDC 17 “Lymphatic, Hematopoietic, Other Malignancies, Chemotherapy and Radiotherapy” but it includes radiotherapy stays, which can be given in a different centre than the “main” patient centre (where all the other treatments were given). Therefore we suggest not to include MDC 17 in the selection of stays to identify patient centre.

Once the selection on the MCD basis is done, a second selection has to be done on the time between the cancer incidence date (from BCR data) and the admission date, to avoid that recurrent cases are selected in place of primary tumour. As only admissions months and years are available in MCD, the selection retains all hospitalisations within 6 months of incidence month (see Table 6).

Table 30. Time windows applied to admission month in MCD data (reference month: incidence month from BCR).

	Source of data	Number of months after the incidence date	Number of months before the admission date
Any hospitalisation in MCD of interest	MCD	6 months	6 months

7.3.2.4 Construction of the algorithm

Based on all pre-analyses discussed above, we propose the following algorithm to attribute each patient to a centre:

1. based on the centre where MDT meeting occurred (taking into account all MDT within 6 months after incidence date, and including those which occurred one month before the incidence date)
2. if there was no MDT, based on the centre where surgery occurred (taking into account all surgeries within 6 months after incidence date, and including also those which were performed one month before the incidence date)
3. if there was no MDT and no surgery, based on the centre where chemotherapy was given (including chemo within 6 months before or after incidence date)
4. if there was no MDT, no surgery and if no chemotherapy was given, based on the per diem lump sums from IMA data (within one month before or after incidence date)
5. if none of the above, based on centre where the patient was hospitalized for a cancer related hospitalisation (in MCD data, within 6 months before or after incidence date)

The fact that MCD data are used in the last step of this algorithm is due to the linkage problems that are specific to this project. When the linkage is good, MCD data could be used as a second or third step in the algorithm.

7.3.3 Results

7.3.3.1 Algorithm for testis cancer

Table 31 presents the percentage of patients for which the centre can be identified for testis cancer patients, by type of nomenclature code (thus based on IMA data only). In 2006, the centre could be identified for 66.1% of the patients based on MDT meeting and for 76.6% based on the surgery code. Chemotherapy can be used to identify the centre in 57.7% of the cases (in 2006). Finally, using the stringent criteria of an admission code within the month of the incidence date led the identification of the centre in 82.7% of the cases (in 2006).

Table 31. Comparison of different ways to identify centre of patients in IMA data (testicular cancer).

	N	Centre can be unequivocally identified based on MDT meeting within 30 days before or 180 after ID (IMA)		Centre can be unequivocally identified based on cancer surgery code within 30 days before or 180 days after ID (IMA)		Centre can be unequivocally identified based on chemotherapy within 180 days before or after ID (IMA)		Centre can be unequivocally identified based on non specific hospital admission code within 30 days before or after ID (IMA)

2006	248	164	66.13	190	76.61	143	57.66	205	82.66
All	1307	523	40.02	972	74.37	673	51.49	1094	83.70

Using this algorithm, 96.4% of the patients can be attributed to a centre based on IMA data exclusively (see Table 32). There is an improvement of the performance of the algorithm over the years, due to the increase in the number of MDT meetings. One can hypothesize that it would even perform better now, when all patients (should) have a MDT meeting.

Table 32. Results of algorithm to identify centre of patients based on IMA data (testis cancer).

	N	Centre can be identified based on IMA data (algorithm)			
		no		yes	
		n	%	n	%
Incidence year					
2001	209	15	7.18	194	92.82
2002	175	7	4.00	168	96.00
2003	214	7	3.27	207	96.73
2004	207	9	4.35	198	95.65
2005	254	4	1.57	250	98.43
2006	248	5	2.02	243	97.98
All	1307	47	3.60	1260	96.40

Table 33 presents the results of the attribution of centre based on MCD data only (data were only linked to MCD for the years 2002, 2003 and 2004). For 2001, some centres can be identified for those patients with incidence date at the end of the year and with hospitalizations in 2002. Globally, the percentages are very low (between 48% and 57%), and reflect the problems in the data linkage. One can hypothesize that these percentages would be much higher, would the linkage problems be resolved.

Table 33. Results of algorithm to identify centre of patients based on MCD data only.

	N	Centre is unequivocally identified based on hospitalisation for testis cancer within 6 months before or after ID (MCD)			
		no		yes	
		N	%	N	%
Incidence year					
2001	209	200	95.69	9	4.31
2002	175	91	52.00	84	48.00
2003	214	93	43.46	121	56.54
2004	207	102	49.28	105	50.72
2005	254	254	100.00	.	.
2006	248	248	100.00	.	.
All	1307	988	75.59	319	24.41

Table 34 tests whether the different approaches to identify centres give the same results (based on patients for which the centre can be unequivocally identified, as explained above). In 95% of the cases, MDT and surgery occurred in the same centre. This percentage is lower for chemo (86%). Also, when centre can be identified based on MCD data, it matches the IMA algorithm in 97% of the cases. This confirms the validity of the IMA algorithm.

Table 34. Check consistency of approaches to identify centres based on administrative data.

Consistency between	N of patients	N of consistent cases	% of consistency
MDT centre and surgery centre	397	377	94.96
MDT centre and chemotherapy	293	251	85.67
MDT centre and lump sum IMA	459	438	95.42
IMA algorithm versus MCD data	316	305	96.52

7.3.3.2 Volume of centres for testis cancer

The results of the above algorithm (only based on IMA data due to the linkage problems) gives the following results for testis cancer (Table 17).

Table 35. Summary measures of volume of centres for testis cancer.

2001-2006	N hospitals	Mean	Median	Std Dev	Minimum	Lower Quartile	Upper Quartile	Maximum
Total patients	105	12.0	8.0	12.3	1.0	5.0	16.0	96.0
Annual volume	105	2.0	1.3	2.1	0.2	0.8	2.7	16.0

Annual volume (2001-2006) category	Frequency	Percent	Cumulative Frequency	Cumulative Percent
<1 /year	33	31.43	33	31.43
1-<2 /year	34	32.38	67	63.81
2-<3 /year	17	16.19	84	80.00
3-<4 /year	9	8.57	93	88.57
>= 4 /year	12	11.43	105	100.00

7.4 METHODS OF ANALYSIS

7.4.1 Descriptive statistics by type of outcome

Continuous variables

Continuous variables (such as the patient age, the number of tumour marker assessments ...) were described with the mean, standard deviation (SD), median, 25th and 75th percentile of their distribution. For the quality indicators, these data were also presented with a box plot. The square of the box includes 50% of the observations (between the lower and the upper quartile, the interquartile range, IQR). The two whiskers (i.e. the vertical bars departing from the square) are drawn down till the last observation below Q1 (first quartile) - 1.5 x IQR and up above Q3 (third quartile) + 1.5 x IQR. The outliers outside those boundaries are located outside the box and indicated with an asterisk. The mean of the distribution is represented by a "+" sign and the median is the horizontal line dividing the box in 2 (if the median is different from Q1 or Q3).

Binary variables

Binary variables (the majority of the quality indicators) were described as percentages (denominator N, numerator n, %). The unit of analysis was most of the time the patient, otherwise explicitly mentioned.

Standardized Incidence Rates

Incidence rates by province were standardized for the age using the direct standardization method. The age structure of the European population was used as the standard ¹¹.

5-year overall survival

Overall 5-year survival curves have been calculated using the Kaplan Meier method, stratifying the curves by pStage. The vital status of each patient at the end of December 2009 was available.

5-year relative survival

The calculation of the disease-specific survival is impossible at present, and the relative survival (i.e. observed survival / expected survival) is calculated as a proxy. Expected survival rates were retrieved from the mortality tables of 2006 (http://statbel.fgov.be/nl/statistiek/cijfers/bevolking/sterfte_leven/tafels/index.jsp) and were linked to the individual patient, taking into account age, gender and region.

7.4.2 Graphical description of the variability per centre (funnel plots)

The variability in outcome results has been described graphically for all quality indicators. The algorithm to attribute a patient to a center has been described in chapter 7.3. Patients who could not be attributed to a centre are not included in these graphics.

7.4.2.1 *Definition of a funnel plot*

The definition of funnel plots has four components. In each unit (hospital), r events are observed out of a sample size n (cross sectional binomial data).

An indicator (summary statistic) which is the observed proportion of event r/n .

A target proportion which is the average event rate θ_0 . It is given by the sum of all events divided by the sum of all sample sizes.

A measure of the precision, in that case given by the unit sample size n .

The control limits that depend of the target θ_0 , of the sample size n and of a given p -value. These limits are constructed such that the chance of exceeding these limits for a « in control » unit is p . Usual sets of values for p are $p=0,001$, $p=0,999$ corresponding to 3 SD (the usual limits in control charts framework), and $p=0,025$, $p=0,975$ corresponding to 2 SD (the usual limits set in the test of hypotheses framework).

In the case of binomial cross sectional data, the limits are given by

$$y_p(\theta_0, n) = \theta_0 + z_p \sqrt{\frac{\theta_0(1-\theta_0)}{n}}, \text{ with } z_p \text{ as such that } P(Z \leq z_p) = p \text{ for a standard normal distribution } Z \text{ (}_{\alpha=0.025} = -1.96).$$

These charts aim to differentiate between « in control » units, showing a common cause of variation, and « out of control » units, exhibiting a special cause of variability, which has then to be investigated further. They show the outcome measure plotted against a measure of its precision, so that control limits form a funnel around the target outcome.

Funnel plots have many advantages: the axes are readily interpretable, so that additional information can be added by hand if desired, the eye is naturally drawn to important points that lie outside the funnels, there is no spurious ranking of institutions, and there is clear allowance of additional variability in institutions with small volume.

7.4.2.2 How to calculate the limits of variability for the funnel plot?

Calculating a confidence interval around a proportion looks like a very simple statistical problem, but is not, as shown by the extensive literature on the subject. A relatively recent review listed 11 available methods to do so, from the easy-to-calculate and widely used normal approximation to the more sophisticated Bayesian interval^g ^h. Confidence intervals typically are classified as being “approximate”, meaning that they make use of the normal approximation of the binomial distribution, or as being “exact”, meaning they are based on the binomial distribution itself. Contrary to what their name suggests, “exact” methods are not unique, and are not necessarily better than “approximate” methodsⁱ.

This methodological note presents the 4 most frequently used methods, describes their advantages and inconveniences, and motivates a choice to compute limits for the funnel plots. In all formulas: $\hat{p} = X / n$ (with X = number of events, n = sample size)

The Wald interval (Normal approximation):

$$CI_{normal} = \hat{p} \pm z_{\alpha/2} \sqrt{\hat{p}(1-\hat{p})/n}$$

Extensive simulations have shown that the normal approximation performs badly. The real coverage can be noticeably smaller than the nominal value (confidence intervals are shorter than what they should be), even for large sample sizes and non extreme probabilities.

The Wilson interval:

$$CI_{Wilson} = \frac{X + z_{\alpha/2}^2 / 2}{n + z_{\alpha/2}^2} \pm \frac{z_{\alpha/2} \sqrt{n}}{n + z_{\alpha/2}^2} \sqrt{\hat{p}(1-\hat{p}) + z_{\alpha/2}^2 / 4n}$$

This interval performs much better than the Wald interval, even for small sample sizes.

^g. Brown L, Cai T, DasGupta A. Interval estimation for a binomial proportion. Statistical science 2001; 16(2): 101-133.

^h. Newcombe RG. Two-sided confidence intervals for the single proportion: comparison of seven methods. Stat Med 1998; 17(8): 857-872.

ⁱ. Agresti A, Coull BA. Approximate is better than 'exact' for interval estimation of binomial proportions. The American Statistician 1998; 52: 119-126.

The Agresti-Coull interval:

$$CI_{AC} = \tilde{p} \pm z_{\alpha/2} \sqrt{\tilde{p}(1-\tilde{p}) / \tilde{n}}$$

$$\text{with } \tilde{X} = X + z_{\alpha/2}^2 / 2, \quad \tilde{n} = n + z_{\alpha/2}^2, \quad \tilde{p} = \tilde{X} / \tilde{n}$$

This interval, a simplified version of the Wilson interval, is appealing because of its simplicity (it has the same form as the Wald interval) and because of its easy-to-remember rule of thumb: “add 2 successes and 2 failures” (using the value 2 instead of 1.96 for z). This method and the Wilson method are often recommended in papers comparing different methods on statistical properties (mainly the real coverage).

The Clopper-Pearson interval:

This interval directly derives the probabilities from the binomial distribution. Because of the connections between the Binomial, the F-distributions and the Beta distributions, a closed form of the confidence limits is given by inverting beta distributions:

$$Lower_{CP} = Beta^{-1}(\alpha / 2, x, N - x + 1)$$

$$Upper_{CP} = Beta^{-1}(1 - \alpha / 2, x + 1, N - x)$$

The common critic on this interval is that its actual coverage probability is at least as large as the nominal level, for any probability, and it can be much larger. This means that these intervals are unnecessarily conservative (unnecessarily large), especially for small sample sizes. Some authors have proposed modifications which lead to better properties, but these methods are computationally intensive and are not (yet) standard available in SAS.

To graphically illustrate the extend of differences between the 4 methods, Figure 19A and B below present the lower confidence limits for an extreme probability (A, $p=0.96$) and for an average probability (B, $p=0.60$). When $p=0.96$, the Wald approximation gives much smaller limits than the three other methods. When $p=0.60$, the Wilson and Agresti-Coull intervals are not discernable, and the Clopper-Pearson interval is the widest.

Figure 19. Lower limit (95%CI) for funnel plot computed for $p=0.96$ (figure above) and $p=0.60$ (figure below).

In conclusion, we suggest to use the Agresti-Coull method, as simulations showed good properties even on small sample sizes. This is also the method used by Zichtbare Zorg in The Netherlandsⁱ.

7.5 TECHNICAL FILES INDICATORS

7.5.1 TCI: Proportion of patients with testicular cancer undergoing tumour marker assessment before any treatment

7.5.1.1 Rationale

According to the guidelines, AFP and HCG should be measured preoperatively to distinguish between seminoma and non-seminoma and to guide postoperative management (expert opinion)⁷. Ideally, this measurement should be as close as possible to the first treatment. The cut-off has been arbitrarily set at 3 months.

7.5.1.2 Numerator

All patients diagnosed with testicular cancer in a given year undergoing tumour marker assessment (HCG and AFP) before any treatment.

7.5.1.3 Denominator

All patients diagnosed with testicular cancer in a given year.

7.5.1.4 Elaboration

Figure 20 provides the algorithm for indicator TCI. From the testicular cancer population, only patients receiving treatment (surgery and/or chemotherapy and/or radiotherapy) are selected (denominator). In this subpopulation, patients undergoing HCG and AFP measurement are identified. Two numerators are calculated:

- The number of patients undergoing the measurement within 3 months before first treatment;
- The number of patients undergoing the measurement within 2 weeks before first treatment.

ⁱ Personal communication, Prof. Damhuis.

Figure 20. Flowchart of indicator TCI.

7.5.1.5 Data source(s)

Source database(s)

- BCR for source population
- IMA and MCD for interventions

Administrative codes

- *Diagnosis of testicular cancer*: ICD-10 code C62 (BCR)
- *Tumour marker assessment*: nomenclature codes (IMA)
- *AFP*: see Table 55
- *HCG*: see Table 55
- *Date of first treatment*:
 - *Surgical treatment*: nomenclature codes (IMA) (Table 60) or ICD-9-CM codes (MCD) (Table 61)
 - *Radiotherapy*: nomenclature codes (IMA) (Table 62)
 - *Chemotherapy*: CNK codes (IMA) (Table 63)

7.5.1.6 Results

For the period 2001 – 2006, 96% (1249/1307) of all patients with testicular cancer underwent treatment. Of the treated patients, 89% (1106/1249) underwent tumour marker assessment. 73% of the treated patients (918/1106) underwent the measurement within 3 months of the first treatment (Table 36), while 50% underwent the measurement within 2 weeks of the first treatment. When analysing the population with coupled BCR-IMA-MCD data, the results are completely in line (Table 37).

Table 36. Proportion of treated patients with testicular cancer undergoing tumour marker assessment within 3 months of first treatment, BCR-IMA data only (2001-2006).

	Numerator	Denominator	Proportion
2001	141	195	72.3
2002	125	165	75.8
2003	141	206	68.4
2004	127	199	63.8
2005	193	247	78.1
2006	191	237	80.6
Total	918	1249	73.5

Table 37. Proportion of treated patients with testicular cancer undergoing tumour marker assessment within 3 months of first treatment, BCR-IMA-MCD data (2002-2004).

	Numerator	Denominator	Proportion
2002	89	117	76.1
2003	95	146	65.1
2004	95	143	66.4
Total	279	406	68.7

The proportion of patients receiving tumour marker assessment within 3 months before treatment start fluctuated between 2001 and 2006. The highest proportions were measured during the last two years of analysis, with more than 80% in 2006.

The variability between centres was investigated for two time frames and revealed no major differences between these time periods (Figure 21 and Figure 22). The number of outliers below the lower limit was 5 for the period 2001-2003 and 6 for the period 2004-2006.

Figure 21. Proportion of treated patients with testicular cancer undergoing tumour marker assessment within 3 months of first treatment, analysis by centre (N=95), period 2001-2003 (BCR-IMA data only).

Figure 22. Proportion of treated patients with testicular cancer undergoing tumour marker assessment within 3 months of first treatment, analysis by centre (N=97), period 2004-2006 (BCR-IMA data only).

7.5.2 TC2: Proportion of patients with testicular cancer undergoing CE-CT or MRI for primary staging

7.5.2.1 *Rationale*

Contrast-enhanced CT of the thorax, abdomen and pelvis is the imaging technique of first choice for the detection of retroperitoneal and mediastinal lymph nodes and pulmonary and hepatic metastases in patients with histopathologically confirmed testicular cancer (2C evidence) ⁷. However, CT is a high radiation-dose examination, and every effort should be made to avoid unnecessary scanning, particularly in young patients. Furthermore, adequate precautions should be taken in order to avoid iodine allergy or nephrotoxicity. For these patients, magnetic resonance imaging (MRI) could be an alternative staging technique (expert opinion). In case a MRI is performed, a CT thorax is also necessary.

7.5.2.2 *Numerator*

All patients diagnosed with testicular cancer in a given year undergoing CE-CT or MRI for primary staging.

7.5.2.3 *Denominator*

All patients diagnosed with testicular cancer in a given year.

7.5.2.4 *Elaboration*

Figure 23 provides the algorithm for indicator TC2. From the testicular cancer population (denominator), patients undergoing CE-CT thorax/abdomen/pelvis or (MRI abdomen/pelvis + CT thorax) are selected. To allow the identification of these imaging tests performed for primary staging reasons, a time limit of 1 month before incidence date and 3 months after incidence date was set (numerator).

Figure 23. Flowchart of indicator TC2.**7.5.2.5 Data source(s)****Source database(s)**

- BCR for source population
- IMA for interventions

Administrative codes

- *Diagnosis of testicular cancer*: ICD-10 code C62 (BCR)
- *Contrast-enhanced CT*: nomenclature codes (IMA) for CT (Table 56), CNK codes for contrast (Table 57)
- *MRI*: nomenclature codes (IMA) (Table 58)

7.5.2.6 Results

Primary staging for testicular cancer encompasses contrast-enhanced CT thorax, abdomen and pelvis or, in particular cases, MRI abdomen and pelvis and CT thorax. However, no specific nomenclature codes were available for CT thorax, abdomen or pelvis, or MRI abdomen or pelvis. Moreover, the identification of contrast-enhanced CT was difficult, since the available codes were not consistently used (the combination of the nomenclature codes for CT and the CNK codes for contrast resulted in zero records). As a result, this indicator was not measurable.

Nevertheless, some results can be calculated using the available administrative data. Of all patients with testicular cancer, 94.8% underwent a CT (of the neck and/or thorax and/or abdomen) and/or a MRI (of the neck and/or thorax and/or abdomen) within 1 month before incidence date and 3 months after incidence date (see also Chapter 4: Descriptive statistics).

7.5.3 TC3: Proportion of patients with testicular cancer discussed at the MDT meeting

7.5.3.1 Rationale

Testicular cancer is a rare cancer and asks for a specialised approach. Discussion of the therapeutic approach in a multidisciplinary setting is necessary, at least involving urologists, medical oncologists, radiotherapists and pathologists. Specific nomenclature codes for a multidisciplinary oncologic consultation are available since February 1st 2003.

7.5.3.2 Numerator

All patients diagnosed with testicular cancer in a given year discussed at the MDT meeting within 6 months after incidence date.

7.5.3.3 Denominator

All patients diagnosed with testicular cancer in a given year.

7.5.3.4 Elaboration

Since a specific code for a MDT meeting only became available since February 1st 2003, patients with incidence date before are excluded (Figure 24). Since there is always a possibility of more than one primary tumour (other than the testicular tumour) and in order to increase the likelihood that the MDT was linked to the testicular tumour, a timeframe of 6 months after the incidence date was chosen.

Figure 24. Flowchart of indicator TC3.

7.5.3.5 Data source(s)

Source database(s)

- BCR for source population
- IMA for interventions

Administrative codes

- *Diagnosis of testicular cancer*: ICD-10 code C62 (BCR)
- *MDT meeting*: nomenclature code (IMA) (Table 59)

7.5.3.6 Results

Of the 907 patients with testicular cancer diagnosed after February 1st 2003, 63.6% (577/907) was discussed at a MDT meeting. In 58.4% of the patients (530/907), the discussion was held within 1 month before and 6 months after the incidence date (Figure 24 and Table 38).

The proportion of patients discussed at a MDT meeting increased over time. In the first year the MDT nomenclature codes were introduced, only about 44% of the patients were discussed in a multidisciplinary setting. In 2006, already more than 67% of the patients were discussed at a MDT meeting, suggesting that the multidisciplinary approach is gaining interest in testicular cancer treatment.

Table 38. Proportion of patients with testicular cancer discussed during a multidisciplinary team meeting, BCR-IMA data, 2003 – 2006.

	Numerator	Denominator	Proportion
2003	88	198	44.4
2004	110	207	53.1
2005	165	254	65.0
2006	167	248	67.3
Total	530	907	58.4

The analysis per centre for the years 2004-2006 shows that for a number of centres no patients could be identified who were discussed at a MDT meeting (using the IMA data) (Figure 25). In total, the number of outliers below the lower limit was 15. Importantly, the absence of a nomenclature code for a MDT meeting for a particular patient does not necessarily mean that no MDT was held. Some centres might not charge MDT meetings and in turn, they do not appear in the IMA database.

Figure 25. Proportion of patients with testicular cancer discussed during a multidisciplinary team meeting, analysis by centre (N=97), period 2004-2006 (BCR-IMA data only).

7.5.4 TC4: Number of annually surgically treated patients with testicular cancer per centre

7.5.4.1 *Rationale*

Several studies indicate a relationship between volume and outcome for testicular cancer^{13, 19, 20}. However, since testicular cancer is a rare cancer, and the number of diagnosed patients in Belgium is low, the calculation of a volume-outcome relationship was considered not feasible. Therefore, it was opted to present the surgical cases by centre.

7.5.4.2 *Definition*

Number of orchidectomies for cancer per centre in a given year.

7.5.4.3 *Elaboration*

Patients undergoing surgery are selected from the testicular cancer population (Figure 26). The analysis is done per centre.

Figure 26. Flowchart of indicator TC4.

7.5.4.4 *Data source(s)*

Source database(s)

- BCR for source population
- IMA and MCD for interventions

Administrative codes

- *Diagnosis of testicular cancer:* ICD-10 code C62 (BCR)
- *Surgical treatment:* nomenclature codes (IMA) (Table 60) or ICD-9-CM codes (MCD) (Table 61)

7.5.4.5 *Results*

In a first attempt to analyse this indicator, only the specific nomenclature codes for testicular surgery were considered, revealing only 923 patients (70.6%) treated with surgery. However, this number seemed to be an underestimation of the real percentage of surgical interventions for testicular cancer. More detailed analyses showed that for a remarkable proportion of patients (N=174), a code for hernia operation (241113, 241124, 241161, 241150) was recorded between one month before and six months after testicular cancer diagnosis. In these cases, because of the time relation between the 'hernia operation' and the diagnosis of testicular cancer, these surgical interventions were considered to be an orchidectomy. As a result, taking both testicular surgery and hernia surgery codes into account, 1097 patients (83.9%) with testicular cancer underwent surgery according to the IMA data (Table 39).

When evaluating the coupled BCR-IMA-MCD data for the available years, a higher proportion of surgically treated patients was observed (Table 40). This higher proportion may be explained by patients for whom either a wrong or no nomenclature code was registered, despite having undergone a surgical intervention for testicular cancer.

Table 39. Proportion of surgically treated patients, BCR-IMA data only (2001-2006).

	Numerator	Denominator	Proportion
2001	170	209	81.3
2002	145	175	82.9
2003	186	214	86.9
2004	173	207	83.6
2005	222	254	87.4
2006	201	248	81.0
Total	1097	1307	83.9

Table 40. Proportion of surgically treated patients, BCR-IMA-MCD data (2002-2004).

	Numerator	Denominator	Proportion
2002	107	122	87.7
2003	137	150	91.3
2004	131	145	90.3
Total	375	417	89.9

In the period 2001-2003, only 6 centres performed more than 10 orchidectomies (Figure 27). This number increased to 13 centres for the period 2004-2006 (Figure 28).

Figure 27. Number of surgically treated patients with testicular cancer by centre, BCR-IMA data (2001-2003).

Figure 28. Number of surgically treated patients with testicular cancer by centre, BCR-IMA data (2004-2006).

7.5.5 TC5: Radiation dose and field in patients with testicular cancer treated with radiotherapy by stage

7.5.5.1 *Rationale*

An overview of the recommendations that relate to radiotherapy in patients with testicular cancer is provided below ⁷:

In patients with stage I seminoma post-orchidectomy, radiotherapy can be considered as a management option (2B evidence);

Patients with stage IIA or IIB seminoma should be treated with chemotherapy or radiotherapy (2C);

In patients with seminoma previously treated with chemotherapy, and who have a residual mass > 3 cm and/or positive PET findings, radiotherapy can be considered (expert opinion).

Depending on the stage, specific radiation schedules and fields are used.

7.5.5.2 *Definition*

Distribution of radiation doses and fields in patients with testicular cancer treated with radiotherapy in a given year, by stage.

7.5.5.3 *Elaboration*

From all patients with testicular cancer, only patients with a known stage are selected to allow a calculation by stage (Figure 29). From these, patients receiving radiotherapy are selected. However, in the absence of administrative data containing technical details on the radiation dose and/or field, the indicator is not measurable.

Figure 29. Flowchart of indicator TC5.

7.5.5.4 Data source(s)

Source database(s)

- BCR for source population
- IMA for interventions

Administrative codes

- *Diagnosis of testicular cancer*: ICD-10 code C62 (BCR)
- *Stage*: BCR
- *Radiotherapy*: nomenclature codes (IMA) (Table 62). However, no dose and field available in administrative databases

7.5.5.5 Results

As stated above, the indicator is not measurable in the absence of administrative data containing information on the radiation dose and field. Nevertheless, an indication can be given on the percentage of patients receiving radiotherapy by stage. Of all 913 patients with a known stage (between 2001 and 2006), 31.8% received radiotherapy (Figure 29). Radiotherapy was most often given in stage I patients (33.7%), and less in stage III (23.5%) or stage II patients (17.8%).

7.5.6 TC6: Proportion of patients with stage I non-seminoma treated with active surveillance

7.5.6.1 *Rationale*

According to the guidelines, primary surveillance is recommended for patients with stage I non-seminoma post-orchidectomy, with treatment at relapse (2B evidence) ⁷.

7.5.6.2 *Numerator*

All patients diagnosed with stage I non-seminoma testicular cancer in a given year, treated with active surveillance.

7.5.6.3 *Denominator*

All patients diagnosed with stage I non-seminoma testicular cancer in a given year.

7.5.6.4 *Elaboration*

In principle, this indicator is calculated by exclusion (Figure 30). From all testicular cancer patients, all patients with non-seminoma morphology and known stage I are selected. From these, all patients not undergoing surgical resection are excluded. From all surgically treated stage I non-seminomata, patients dying within 6 months after surgery are excluded (denominator). Finally, within this group, patients not undergoing chemotherapy and/or radiotherapy within 6 months after surgery are considered to be treated with active surveillance (numerator).

Figure 30. Flowchart of indicator TC6.

7.5.6.5 Data source(s)

Source database(s)

- BCR for source population
- IMA for interventions

Administrative codes

- *Diagnosis of testicular cancer*: ICD-10 code C62 (BCR)
- *Stage*: BCR
- *Non-seminoma histology*: BCR
- *Surgical treatment*: nomenclature codes (IMA) (Table 60) or ICD-9-CM codes (MCD) (Table 61)
- *Radiotherapy*: nomenclature codes (IMA) (Table 62)
- *Chemotherapy*: CNK codes (IMA) (Table 63)
- *Tumour markers*: nomenclature codes (IMA) (Table 55)
- *CT*: nomenclature codes (IMA) (Table 56)

7.5.6.6 Results

Of all patients with testicular cancer, 46.7% (611/1307) were found to have a non-seminoma morphology. Of these, 54.3% (332/611) had known stage I disease. Of all patients with stage I non-seminoma, 87.6% (291/332) were treated with orchidectomy. Within six months after surgery, no deaths were recorded, but for five patients the vital status could not be retrieved. Of the remaining 286 patients, 69 (24.1%) were not treated with chemotherapy or radiotherapy within 6 months after surgical treatment, and can be considered to be treated with active surveillance (Table 41).

The proportion of patients entering an active surveillance program was relatively stable over time, apart from a peak in 2003. Data for 2006 need to be interpreted with caution, because nomenclature data after 2006 were not included in this study. Therefore, an overestimation of patients treated with active surveillance may be possible for 2006.

When evaluating the coupled BCR-IMA-MCD data for the available years, a slightly higher proportion of patients treated with active surveillance was observed for the years 2002 and 2003 (Table 42).

Table 41. Proportion of patients with stage I non-seminoma on active surveillance, BCR-IMA data (2001-2006).

	Numerator	Denominator	Proportion
2001	7	26	28.0
2002	6	36	17.1
2003	17	46	37.0
2004	11	51	22.0
2005	16	69	23.5
2006	12	58	20.0
Total	69	286	24.1

Table 42. Proportion of patients with stage I non-seminoma on active surveillance, BCR-IMA-MCD data (2002-2004).

	Numerator	Denominator	Proportion
2002	8	29	27.6
2003	16	39	41.0
2004	9	40	22.5
Total	33	108	30.6

The analyses per centre were comparable for the two investigated time frames (Figure 31 and Figure 32). A high variability was found, with centres achieving 0% and 100% active surveillance practice.

Figure 31. Proportion of patients with stage I non-seminoma on active surveillance, analysis per centre (N=56), period 2001-2003 (BCR-IMA data only)*.

* Several centres only treated 1 or 2 patients with stage I non-seminoma, resulting in overlapping point estimates for these centres.

Figure 32. Proportion of patients with stage I non-seminoma on active surveillance, analysis per centre (N=67), period 2004-2006 (BCR-IMA data only)*.

* Several centres only treated 1 or 2 patients with stage I non-seminoma, resulting in overlapping point estimates for these centres.

Because of the somewhat surprisingly low number of stage I non-seminoma patients treated with active surveillance, the calculation of this indicator was repeated using an adapted definition. As many recurrences already occur within 6 months after orchidectomy, treatment started at least 3 months after orchidectomy was considered to be because of a recurrence, while treatment started within 3 months after orchidectomy was considered to be adjuvant.

Using this adapted definition, the proportion of stage I non-seminoma patients treated with active surveillance was found to be 28.7% for the period 2001-2006 (using BCR-IMA data only), which is only slightly higher than the original result. The funnel plots did not change importantly and are therefore not shown.

7.5.7 TC7: Proportion of patients receiving CE-CT or MRI for residual disease assessment at the end of systemic treatment

7.5.7.1 *Rationale*

According to the guidelines, contrast-enhanced CT scan is recommended for the imaging of residual masses after systemic treatment of testicular cancer (expert opinion)⁷. However, CT is a high radiation-dose examination, and every effort should be made to avoid unnecessary scanning, particularly in young patients. Furthermore, adequate precautions should be taken in order to avoid iodine allergy or nephrotoxicity. For these patients, magnetic resonance imaging (MRI) could be an alternative staging technique (expert opinion). In case a MRI is performed, a CT thorax is also necessary.

7.5.7.2 *Numerator*

All patients diagnosed with metastatic testicular cancer in a given year (stage II or higher), having received systemic treatment, undergoing assessment for residual disease with CE-CT or MRI.

7.5.7.3 *Denominator*

All patients diagnosed with metastatic testicular cancer in a given year (stage II or higher), having received systemic treatment.

7.5.7.4 *Elaboration*

From all patients with testicular cancer, all patients with metastatic disease (stage II or III) are selected (Figure 33). Within this group, patients treated with chemotherapy are selected. Finally, patients undergoing CE-CT thorax/abdomen/pelvis or (MRI abdomen/pelvis + CT thorax) within 6 months after the end of systemic treatment are selected. However, since the nomenclature codes for CT and MRI do not specify the anatomical location, the indicator is not measurable.

Figure 33. Flowchart of indicator TC7.**7.5.7.5 Data source(s)****Source database(s)**

- BCR for source population
- IMA

Administrative codes

- *Diagnosis of testicular cancer*: ICD-10 code C62 (BCR)
- *Stage*: BCR
- *Chemotherapy*: CNK codes (IMA) (Table 63)
- *CT*: nomenclature codes (IMA) (Table 56)
- *MRI*: nomenclature codes (IMA) (Table 58)

7.5.7.6 Results

Of the 1307 patients with testicular cancer, 8.2% (107/1307) were found to have known stage II or III disease. Of these, 90.7% (97/107) were treated with chemotherapy. Restaging after chemotherapy is ideally performed with contrast-enhanced CT thorax, abdomen and pelvis or, in case of contra-indications, MRI abdomen-pelvis and CT thorax. However, no specific nomenclature codes were available for CT thorax or abdomen or pelvis, or MRI abdomen-pelvis. Moreover, the identification of contrast-enhanced CT was difficult, since the available codes for contrast were not consistently used (the combination of the nomenclature codes for CT and the CNK codes for contrast resulted in zero records). As a result, this indicator could not be assessed.

Nevertheless, some results can be calculated using the available administrative data. Of the stage II/III patients treated with chemotherapy, 53.6% (52/97) underwent a CT (of the neck and/or thorax and/or abdomen) and/or a MRI (of the neck and/or thorax and/or abdomen) within 6 months after the end of the chemotherapy.

7.5.8 TC8: Degree and duration of active surveillance in patients with stage I NSGCT or SGCT

7.5.8.1 *Rationale*

The guidelines on testicular cancer contain the following recommendations on the use of tumour markers during active surveillance in patients with stage I NSGCT or SGCT⁷:

In patients with stage I non-seminoma under primary surveillance, physical examination and blood serum marker tests (AFP, HCG, LDH) should be conducted every month in the first year, every two months in the second year, every three months in the third year, and every six months in the fourth and fifth years (expert opinion);

Although the evidence is insufficient to propose a standard scheme for CT follow-up in patients with stage I non-seminoma under primary surveillance, at least an abdomino-pelvic CT at 3 and 12 months is recommended (2B);

In patients with stage I seminoma under primary surveillance, physical examination and blood serum marker tests (AFP, HCG, LDH) should be conducted every 3 months in the first and second years, and every six months in the third, fourth and fifth years (expert opinion);

Although the evidence is insufficient to propose a standard scheme for CT follow-up in patients with stage I seminoma under primary surveillance, at least an abdomino-pelvic CT every 6 months during the 2 first years post-orchidectomy is desirable (expert opinion).

7.5.8.2 *Numerator*

Number of patients from the denominator with:

- 12 measurements of AFP and HCG in the first year post-orchidectomy for NSGCT and 4 measurements for SGCT (+ frequency tables)
- 2 CT or MRI in the first year post-orchidectomy (+ frequency tables)

7.5.8.3 *Denominator*

All patients diagnosed with stage I testicular cancer in a given year, not treated with chemotherapy or radiotherapy within 6 months post-orchidectomy.

7.5.8.4 *Elaboration*

The algorithm of the present indicator follows the same logic as that of indicator TC6 (Figure 30). First, all patients with stage I disease are selected (Figure 34). Next, patients undergoing surgery are selected. From this selection, patients dying within 6 months after surgery and/or receiving radio- and/or chemotherapy within 6 months after surgery are excluded. The resulting selection are stage I patients undergoing primary surveillance. In this selection, a distinction is made between seminoma and non-seminoma morphology. Finally, frequency tables are constructed for the number of CE-CT thorax/abdomen/pelvis or (MRI abdomen/pelvis + CT thorax) on the one hand and tumour markers (AFP and HCG) on the other hand.

7.5.8.5 Data source(s)

Source database(s)

- BCR for source population
- IMA for interventions

Administrative codes

- *Diagnosis of testicular cancer*: ICD-10 code C62 (BCR)

- *MRI*: nomenclature codes (IMA) (Table 58)

7.5.8.6 Results

Of all patients with testicular cancer, 61.7% (806/1307) had known stage I disease. Of these, 86.1% (694/806) underwent surgery. Of the 680 patients who were still alive within 6 months after surgery, 144 (21.2%) were treated with active surveillance. Of these, 75 had seminoma and 69 had non-seminoma (Figure 34).

According to the national guidelines, active surveillance should encompass regular tumour marker assessment and imaging. Concerning imaging, the lack of specificity of the codes for CT and MRI prevented the determination of this indicator (see also above). On the other hand, the degree and duration of tumour marker assessment after surgery could be determined.

The results show that the mean number of tumour marker assessments decreases by follow-up period, as expected (Table 43, Table 44, Figure 14 and Figure 15). However, the mean number of tumour marker assessments by follow-up period fluctuated between 2001 and 2005. For seminomas, the mean number of tumour marker assessments during the first year after surgery approached the recommended number of 4 in 2002 (mean 3.89, SD 3.55), and started to increase since then (Table 43). For non-seminomas, the mean number of tumour marker assessments during the first year after surgery fluctuated between 10.5 and 14.6 during the time period 2001-2004 (Table 44). In 2005, it dropped to 8.9 (SD 8.4).

Figure 36. Number of tumour marker assessments per patient according to follow-up period, non-seminoma, 2001-2005.

As for indicator TC6, the analysis of this indicator was repeated using an adapted definition of active surveillance (i.e. no treatment within 3 months after orchidectomy). Using this adapted definition, 27% of the patients with known stage I disease (seminoma and non-seminoma) and with a surgical nomenclature code and information on vital status available were considered to be on active surveillance between 2001 and 2006. With this adapted definition, the mean number of tumour marker assessments by follow-up period only slightly changed for seminomas (first year after surgery: between 3.86 in 2003 and 6.79 in 2005) (Table 45). However, for non-seminomas clearly higher mean numbers were found in comparison with the first analysis (first year after surgery: between 9.60 in 2005 and 15.88 in 2001) and a decreasing trend became more clearly apparent (Table 46).

7.5.9 TC9: Proportion of patients with relapsing testicular cancer after curative treatment that are included in a clinical trial

7.5.9.1 *Rationale*

The evidence on the treatment of relapsing or refractory disease is mainly limited to observational studies. Some RCTs exist on the use of high-dose chemotherapy, but this treatment is not recommended outside a clinical trial ⁷.

7.5.9.2 *Numerator*

All patients with relapsing testicular cancer after curative treatment in a given year, included in a clinical trial.

7.5.9.3 *Denominator*

All patients with relapsing testicular cancer after curative treatment in a given year.

7.5.9.4 *Elaboration*

From all patients with testicular cancer, all patients undergoing treatment are selected. Since no administrative code exists for recurrence, patients are considered to have a recurrence if new treatment is started at least 6 months after the first treatment. Within this group, patients included in a clinical trial are identified.

Figure 37. Flowchart of indicator TC9.

7.5.9.5 Data source(s)

Source database(s)

- BCR for source population
- IMA: relapse (defined as re-treatment at least 6 months after previous treatment)

Administrative codes

- *Diagnosis of testicular cancer*: ICD-10 code C62 (BCR)
- *Surgical treatment*: nomenclature codes (IMA) (Table 60) or ICD-9-CM codes (MCD) (Table 61)
- *Radiotherapy*: nomenclature codes (IMA) (Table 62)
- *Chemotherapy*: CNK codes (IMA) (Table 63)
- *Inclusion in clinical trial*: no data available

7.5.9.6 Results

For the period 2001 – 2006, 95.5% (1249/1307) of all patients with testicular cancer underwent treatment. Of the treated patients, 6.5% (81/1249) received new treatment at least 6 months after the first treatment. However, no code exists to identify those patients who are included in a clinical trial.

7.5.10 TC10: Overall 5-year survival by stage

7.5.10.1 Rationale

Numerous clinical studies have conclusively demonstrated the effectiveness of testicular cancer treatment in improving survival^{21, 22}.

7.5.10.2 Numerator

All patients diagnosed with testicular cancer in a given year, surviving 5 years after diagnosis, by stage.

7.5.10.3 Denominator

All patients diagnosed with testicular cancer in a given year, by stage.

7.5.10.4 Elaboration

For the calculation of survival statistics, it is essential to include only those patients with a follow-up of the date of death (Figure 38). Mortality data are collected from the mortality database of the sickness funds, and are available until December 31st 2009 for the present study. To calculate the period between the incidence and mortality date, it is of course essential to have the incidence date.

Figure 38. Flowchart of indicator TCI0 and TCI1.**7.5.10.5 Data source(s)****Source database(s)**

- BCR for source population
- IMA
- Kruispuntbank for mortality data

Administrative codes

- *Diagnosis of testicular cancer*: ICD-10 code C62 (BCR)
- *Stage*: BCR
- *Incidence date*: algorithm BCR
- *Mortality date*: Kruispuntbank

7.5.10.6 Results

For almost 70% of the patients (913/1307) the pStage was known. Of these, the majority (898/913) had a known vital status. These patients formed the population to calculate the survival statistics by stage. Especially for stage I and II, the observed survival is high, with a 5-year survival of 97% and 95% respectively (Table 47). For pStage III patients, 5-year survival was found to be 71%. In pStage X, 43 patients died within 5 years after diagnosis, resulting in a 1-year survival of 93%, a 3-year survival of 91% and a 5-year survival of 90%.

Table 47. Observed survival by pStage.

		N	Deaths	Overall survival (%)				
				1 year	2 year	3 year	4 year	5 year
pStage	I	793	27	0.99	0.98	0.97	0.97	0.97
	II	72	3	0.97	0.96	0.95	0.95	0.95
	III	33	10	0.91	0.76	0.74	0.71	0.71

When considering the morphology, no obvious differences were found between the 5-year observed survival of seminomas and non-seminomas (94% vs. 93%) (Table 48 and Figure 39).

Table 48. Observed survival by morphology (pStage X included).

	N	Deaths	Overall survival (%)				
			1 year	2 year	3 year	4 year	5 year
Seminoma	685	41	0.97	0.96	0.95	0.94	0.94
Non-seminoma	603	42	0.96	0.94	0.94	0.93	0.93

Figure 39. Kaplan-Meier curve for observed survival, N=1288.

Overall, the observed survival slightly increased between 2001 (91%) and 2004 (94%) (Table 49).

Table 49. Evolution of observed survival, 2001-2004, N=1288.

2001	2002	2003	2004
0.91	0.93	0.95	0.94

The analysis by centre shows a high proportion of centres achieving a 5-year survival of 100% for pStage I patients (Figure 40). Nevertheless, some centres clearly achieved worse survival rates (9 centres below the lower limit). The number of patients and events in pStage II and III were too small for the analysis by centre.

Figure 40. Observed 5-year survival by centre, N=1288.

7.5.11 TC11: Disease-specific 5-year survival by stage

7.5.11.1 Rationale

See indicator TC10.

7.5.11.2 Numerator

All patients diagnosed with testicular cancer in a given year, surviving 5 years after diagnosis or dying due to a non-testicular-cancer-related cause, by stage and by re-treatment.

7.5.11.3 Denominator

All patients diagnosed with testicular cancer in a given year, by stage.

7.5.11.4 Elaboration

The calculation of the disease-specific survival is impossible at present, because of the absence of national data on reasons of death. Therefore, the relative survival (i.e. observed survival / expected survival) is calculated as a proxy. Expected survival rates were retrieved from the mortality tables of 20046(http://statbel.fgov.be/pub/home_nl.asp#3) and were linked to the individual patient, taking into account age, gender and region.

The same algorithm as for indicator TC10 is followed (Figure 38).

7.5.11.5 Data source(s)

Source database(s)

- BCR for source population
- IMA
- Kruispuntbank for mortality data

Administrative codes

- *Diagnosis of testicular cancer*: ICD-10 code C62 (BCR)
- *Stage*: BCR
- *Incidence date*: algorithm BCR
- *Mortality date*: Kruispuntbank
- *Expected survival*: mortality tables (StatBel)

7.5.11.6 Results

In parallel to the observed survival, the relative survival is also high (Table 50). Even in patients with pStage III disease the relative 5-year survival is 76%. As for the observed survival, no difference in relative survival was found between seminomas and non-seminomas (Table 51). Also for relative survival a slight increase was found between 2001 and 2004 (Table 52).

Table 50. Relative survival by pStage.

		N	Deaths	Overall survival (%)				
				1 year	2 year	3 year	4 year	5 year
pStage	I	793	27	0.99	0.98	0.98	0.97	0.97
	II	72	3	0.99	0.96	0.96	0.95	0.95
	III	33	10	0.91	0.91	0.76	0.76	0.76

Table 51. Relative survival by morphology (pStage X included).

	N	Deaths	Overall survival (%)				
			1 year	2 year	3 year	4 year	5 year

7.5.12 TC12: Disease-free 5-year survival by stage

7.5.12.1 Rationale

Numerous clinical studies have conclusively demonstrated the effectiveness of testicular cancer treatment in improving disease-free survival ²¹.

7.5.12.2 Numerator

All patients diagnosed with testicular cancer in a given year, surviving 5 years after diagnosis and free of disease, by stage.

7.5.12.3 Denominator

All patients diagnosed with testicular cancer in a given year, by stage.

7.5.12.4 Elaboration

The same logic is followed as for indicators TC10 and TC11 (Figure 41). However, to calculate the disease-free survival, the disease status is a necessary parameter. As previously stated, patients are considered to have a recurrence if new treatment is started at least 6 months after the first treatment. These patients, together with deceased patients are censored from the survival analysis.

Figure 41. Flowchart of indicator TCI2.**7.5.12.5 Data source(s)****Source database(s)**

- BCR for source population
- IMA for interventions
- Kruispuntbank for mortality data

Administrative codes

- *Diagnosis of testicular cancer*: ICD-10 code C62 (BCR)
- *Stage*: BCR
- *Incidence date*: algorithm BCR
- *Mortality date*: Kruispuntbank
- *Disease activity*: re-treatment is considered a proxy for relapse

7.5.12.6 Results

In the absence of a code for recurrence in the BCR database, the number of patients with a re-treatment 6 months after first treatment was chosen as a proxy measure. For all patients, in which the pStage was known (N=913) and who were alive at December 31st 2009 (N=858), disease-free survival was calculated. Re-treatment occurred in 20 patients (2.4%) (Figure 41). However, the number of events by pStage was too small to allow a calculation of the disease-free survival by pStage. Therefore, the calculation was done for the entire population (with a known vital status, N=1288).

In alignment with the observed and relative survival rates, the disease-free survival was high (96% after 5 years) (Table 53). For some smaller centres, lower disease-free survival rates were detected (Figure 42). Three centres were found to be below the lower limit.

Table 53. Disease-free survival, 2001-2004, N=1288.

	1 year	2 year	3 year	4 year	5 year
Disease-free survival*	0.99	0.98	0.98	0.97	0.96

* pX stage included.

Figure 42. Disease-free 5-year survival by centre, N=1288.

Using the adapted definition of recurrence as discussed above, the disease-free survival slightly worsened as expected (Table 54). However, the variability across the centres did not change importantly (data not shown).

Table 54. Disease-free survival, 2001-2004, N=1288. Adapted definition.

	1 year	2 year	3 year	4 year	5 year
Disease-free survival*	0.99	0.98	0.97	0.96	0.94

7.6 ADMINISTRATIVE CODES

7.6.1 Diagnosis and staging

Table 55. Nomenclature codes for tumour markers.

Codes	Omschrijving
AFP	
433031 – 433042	Doseren van alfa foetoproteïne (Maximum 1) (Cumulregel 302, 64) Klasse 14
433716 – 433720	Doseren van alfa foetoproteïne (Maximum 1) (Cumulregel 52) Klasse 15
541413 – 541424	Doseren van alfa foetoproteïne met niet isotopen-methode (Maximum 1) (Cumulregel 302, 64) Klasse 14
545156 – 545160	Doseren van alfa foetoproteïne (Maximum 1) (Cumulregel 52) Klasse 15
HCG	
434630 – 434641	Doseren van humane choriogonadotrofines (hCG) (Maximum 1) (Cumulregel 37, 322) (Diagnoseregul 6) Klasse 16
436111 – 436122	Exclusief en specifiek doseren van de vrije Beta-subeenheid van humane choriogonadotrofines (hCG) (Maximum 1) (Cumulregel 37, 201, 124, 125) (Diagnoseregul 45, 46) Klasse 20
546195 – 546206	Doseren van humane choriogonadotrofines (hCG) (Maximum 1) (Cumulregel 37, 322) (Diagnoseregul 6) Klasse 16
548472 – 548483	Exclusief en specifiek doseren van de vrije beta-subeenheid van humane choriogonadotrofines (hCG) (Maximum 1) (Cumulregel 37, 201, 124, 125) (Diagnoseregul 45, 46) Klasse 20

Table 58. Nomenclature codes for MRI.

Codes	Omschrijving
459410 – 459421	NMR-onderzoek van de hals of van de thorax of van het abdomen of van het bekken, minstens drie sequenties, met of zonder contrast, met registratie op optische of elektromagnetische drager

Table 59. Nomenclature codes for multidisciplinary team meeting.

Codes	Omschrijving
350372 – 350383	Schriftelijk verslag van een multidisciplinair oncologisch consult met deelname van minstens drie geneesheren van verschillende specialismen onder leiding van een geneesheer-coördinator, met beschrijving van de diagnose en van het behandelingsplan
350394 – 350405	Deelname aan multidisciplinair oncologisch consult
350416 – 350420	Deelname aan multidisciplinair oncologisch consult door de behandelende arts die geen deel uitmaakt van de ziekenhuisstaf

7.6.2 Surgery

Table 60. Nomenclature codes for orchidectomy.

Codes	Omschrijving
261111 – 261122	Radicale orchidectomie voor primaire testistumour met inguinale en/of iliacale en/of lumbale lymfadenectomie
261096 – 261100	Bilaterale orchidectomie

Table 61. ICD-9-CM codes for orchidectomy.

ICD-9-CM Code	Omschrijving
62.3	Unilateral orchiectomy Orchidectomy (with epididymectomy) NOS
62.4	Bilateral orchiectomy Male castration Radical bilateral orchiectomy (with epididymectomy) Code also any synchronous lymph node dissection (40.3, 40.5)
62.41	Removal of both testes at same operative episode Bilateral orchidectomy NOS
62.42	Removal of remaining testis Removal of solitary testis

7.6.3 Radiotherapy

Table 62. Nomenclature codes for radiotherapy.

Codes	Commentaar
440016 – 440020	Behandeling (één of meer lokalisaties) met hoge energie of gammatherapie (betatron, lineaire accelerator, telekobalt) : In een dienst die beschikt over telekobalt én een een simulator én een dosimetriesysteem met computer (min 20 zittingen)
440053 – 440064	Behandeling (één of meer lokalisaties) met hoge energie of gammatherapie (betatron, lineaire accelerator, telekobalt) met maskers of individuele beschermingsmiddelen bij specifieke indicaties: In een dienst die beschikt over telekobalt én een een simulator én een dosimetriesysteem met computer (min 20 zittingen)
444113 – 444124	Forfaitair honorarium voor een eenvoudige uitwendige bestralingsreeks van 1 tot 10 fracties voor een patiënt die beantwoordt aan de criteria of lijdt aan een aandoening opgenomen in categorie 1 (zie KB 19APR2001)
444135 – 444146	Forfaitair honorarium voor een eenvoudige uitwendige bestralingsreeks van 11 tot 35 fracties voor een patiënt die beantwoordt aan de criteria of lijdt aan een aandoening opgenomen in categorie 2 (zie KB 19APR2001)
444150 – 444161	Forfaitair honorarium voor een complexe uitwendige bestralingsreeks voor een patiënt die beantwoordt aan de criteria of lijdt aan een aandoening opgenomen in categorie 3 (zie KB 19APR2001)
